But we saw that, for any natural motion, the unintegrated part of $\delta A$ necessarily vanishes. Thus, as $\theta$, $\phi$, $\psi$ . . . . , and, therefore, their variations, are by their very nature independent of one another, the vanishing of the unintegrated part gives us one equation of motion for each degree of freedom, the type being in all of them the same, viz.,

$$\frac{d}{dt}\left(\frac{dT}{d\dot\theta}\right)-\left(\frac{dT}{d\theta}\right)+\left(\frac{dV}{d\theta}\right)=0.$$

To exemplify the use of these equations we will take again a few of the more important cases of constraint already treated, and will then proceed to some others of interest as well as of somewhat greater complexity. Examples.

In the simple pendulum, $l$ being again the length of the string, and $\theta$ the inclination to the vertical at time $t$, we have obviously

$$T=\tfrac{1}{2}ml^2\dot\theta^2,\quad V=C-mgl\cos\theta.$$

Hence
$$\left(\frac{dT}{d\dot\theta}\right)=ml^2\dot\theta,\quad \left(\frac{dT}{d\theta}\right)=0,\quad \left(\frac{dV}{d\theta}\right)=mgl\sin\theta.$$

Thus the equation of motion is

$$ml^2\ddot\theta+mgl\sin\theta=0$$

or
$$\ddot\theta+\frac{g}{l}\sin\theta=0,$$

as in § 134.

Suppose the same pendulum to be moving anyhow, $\theta$ still denoting its inclination to the vertical, and $\phi$ denoting the azimuth of the plane in which it is displaced, we have

$$T=\tfrac{1}{2}ml^2(\dot\theta^2+\sin^2\theta.\dot\phi^2),\quad V=C-mgl\cos\theta$$

These give at once

$$\left(\frac{dT}{d\dot\theta}\right)=ml^2\dot\theta,\quad \left(\frac{dT}{d\theta}\right)=ml^2\sin\theta\cos\theta.\dot\phi^2,\quad \left(\frac{dV}{d\theta}\right)=mgl\sin\theta$$

$$\left(\frac{dT}{d\dot\phi}\right)=ml^2\sin^2\theta.\dot\phi,\quad \left(\frac{dT}{d\phi}\right)=0,\quad \left(\frac{dV}{d\phi}\right)=0.$$

Hence the two equations are

$$\ddot\theta-\sin\theta\cos\theta.\dot\phi^2+\frac{g}{l}\sin\theta=0,$$

$$\frac{d}{dt}(\sin^2\theta.\dot\phi)=0.$$

Pendulum with extensible cord.

Still keeping to easy examples, suppose the cord of the ordinary simple pendulum to be extensible, according to Hooke's law. Let $\lambda$ be its length at time $t$. Then the tension is $E(\lambda - l)/l$, and the work it can do in contracting is the integral of this with regard to $\lambda$ from $l$ to $\lambda$, *i.e.*,

$$E(\lambda - l)^2/2l .$$

Hence we have
$$V = C + E(\lambda - l)^2/2l - mg\lambda\cos\theta ,$$
$$T = \tfrac{1}{2}m(\lambda^2\dot\theta^2 + \dot\lambda^2) .$$

Thus Lagrange's equations become

$$\frac{d}{dt}(\lambda^2\dot\theta) + g\lambda\sin\theta = 0 ,$$

$$m\ddot\lambda - m\lambda\dot\theta^2 + E(\lambda - l)/l - mg\cos\theta = 0 ;$$

equations which could be obtained immediately from the application of the second law, with the help of the kinematical expressions for accceleration perpendicular to, and along, the radius-vector of a plane curve (§ 47).

Instead of the complex pendulum treated in § 177, we will now take the case of two masses attached at different points to an elastic string, or light helical spring, and consider their *vertical* vibrations.

Let $a$, $b$ be the unstretched lengths of the parts of the string, M and $m$ the masses. Then if $\xi$, $\eta$ be the vertical displacements at time $t$, we have

$$T = \tfrac{1}{2}(M\dot\xi^2 + m(\dot\xi + \dot\eta)^2) ,$$
$$V = \frac{E}{2}\left(\frac{\xi^2}{a} + \frac{\eta^2}{b}\right) - Mg\xi - mg(\xi + \eta) ;$$

so that Lagrange's equations are

$$\frac{d}{dt}(M\dot\xi + m(\dot\xi + \dot\eta)) + E\frac{\xi}{a} - (M + m)g = 0 ,$$
$$\frac{d}{dt}(m(\dot\xi + \dot\eta)) + E\frac{\eta}{b} - mg = 0 .$$

The equilibrium positions are found by supposing the accelerations to vanish, so that, if we suppose $\xi$ and $\eta$ to be measured from them, the terms in $g$ will disappear. Hence the solution is of exactly the same nature as that already given for an apparently different problem (§ 178).

Setting a watch.

We may mention that equations practically the same as these are obtained when we consider the motions of a watch and its balance-wheel, the watch being supported in a horizontal position by means of a wire, and oscillating in its own plane by the torsion-elasticity of the wire. The reader of § 242 below will have no difficulty in obtaining this result. It suggests a practical method of "setting" a watch to true time, without turning the hands forward or backward, and without letting it run down.

Transference of energy.

The following is a simple, but very instructive, example of the transference of energy (back and forward) between two parts of a system. Two bar-magnets of equal mass, length, and strength (fig. 58), are supported horizontally by pairs of parallel strings, so that when at rest they are in one line. One of them is slightly displaced in the direction of its length, find the subsequent motion of both.[1]

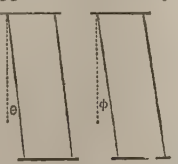

Fig. 58.

If we can, by any process, find two fundamental states of motion which, once established, will be permanent, any other possible motion of the system will be a superposition of these two. The amplitudes and phases in the components may have any values, so long as the whole disturbance is small. This follows from the fact that the system has two degrees of freedom only,—since we are concerned only with motions in the plane of the figure.

(A) Now one obviously possible motion is a simple harmonic vibration of the whole, without change of distance between the magnets. The period of this vibration is obviously the same as that of either magnet if the other were removed.

(B) Another obviously possible motion is that in which the magnets are, at every instant, equally and oppositely deflected. The period of this oscillation will be less or greater than that of the former according as the poles attract or repel one another.

Now the initial state of motion proposed evidently consists of the superposition of (A) and (B) in such a way that there is, at starting, no displacement of either mass, but a definite velocity of one of them only. This corresponds to simultaneous zero of displacement, with equal velocities, for each of (A) and (B). There is therefore at that instant no displacement of either mass; and one is at rest while the other is moving with double the assigned velocity. If $2\pi/n$, $2\pi/n'$ be the periods of the two motions, it is obvious that after the time $\pi/(n - n')$ the magnets will have interchanged their states so that the arrangement will present exactly the same appearance as at first, *if looked at from the other side.*

Let $a$ be the distance between the ends of the bars when all four strings are vertical. Then, if $\theta$, $\phi$ be at time $t$ the inclinations of the pairs of strings to the vertical, $a$ becomes

$$D = a + l(\phi - \theta) ,$$

where $l$ is the common length of the strings. The expression for the potential energy due to magnetism is of the form $\mu/D$, where $\mu$ is positive if like poles be turned to one another.

Hence

$$T = \tfrac{1}{2}ml^2(\dot\theta^2 + \dot\phi^2) ,$$
$$V = \tfrac{1}{2}mgl(\theta^2 + \phi^2) + \frac{\mu}{a + l(\phi - \theta)} .$$

Forming the equations as usual, and omitting powers of $\theta$ and $\phi$ above the first, we have

$$ml^2\ddot\theta = -mgl\theta + \frac{\mu l}{a^2}\left(1 - \frac{2l}{a}(\phi - \theta)\right) ,$$
$$ml^2\ddot\phi = -mgl\phi - \frac{\mu l}{a^2}\left(1 - \frac{2l}{a}(\phi - \theta)\right) ;$$

from which the results already given may be deduced.

Finally, let us take the case of Atwood's machine (§ 173) when Atwood's the masses are equal, and one of them is vibrating through small machine. arcs.

Let $r$, $\theta$ be the polar coordinates of the vibrating mass; then, One mass neglecting powers of $\theta$ higher than the second, we have the general- vibrating. ized equations

$$2\dot r - r\dot\theta^2 = -\tfrac{1}{2}g\theta^2 ,$$
$$\frac{d}{dt}(r^2\dot\theta) = -gr\theta .$$

Put $\frac{1}{2}gr$ for $r$, and $\theta\sqrt{2}$ for $\theta$, and we get

$$\ddot r - r\dot\theta^2 = -\theta^2 ,$$
$$\frac{1}{r}\frac{d}{dt}(r^2\dot\theta) = -2\theta .$$

Transform to rectangular coordinates in the plane of motion, $x$ being vertically downwards; then

$$\ddot x = y^2/x^3 , \qquad \ddot y = -2y/x .$$

This shows that the vertical acceleration of the vibrating particle is very small, but constantly downward. Hence the energy of the vibratory motion is steadily converted into energy of translation of the masses.

When both the equal masses vibrate through small arcs, it is found that the mass whose angular range is the greater has downward acceleration with diminishing angular range. Hence it would appear that, if the string be long enough, the entire motion would be periodic.

§ 216. Before leaving this subject we may form, from the complete value of $\delta A$ given in last section, the generalized equations corresponding to those of Hamilton's "varying action," as given in § 204.

We have at once

$$\left(\frac{dA}{d\dot\theta}\right) = \left(\frac{dT}{d\dot\theta}\right), \left(\frac{dA}{d\dot\phi}\right) = \left(\frac{dT}{d\dot\phi}\right), \ldots, \left(\frac{dA}{d\dot H}\right) = t .$$

But, by the value of T, we have

$$\left(\frac{dT}{d\dot\theta}\right) = P\dot\theta + Q\dot\phi + \ldots$$
$$\left(\frac{dT}{d\dot\phi}\right) = Q\dot\theta + R\dot\phi + \ldots$$
$$\&c. = \&c.$$

[1] We suppose the bars to be so long, in comparison with the distance between them, that we need take account only of the action of their poles which are turned towards one another.

These equations give $\theta, \phi, \ldots$ as homogeneous linear functions of $\left(\frac{dT}{d\theta}\right), \left(\frac{dT}{d\phi}\right), \ldots$ that is, of $\left(\frac{dA}{d\theta}\right), \left(\frac{dA}{d\phi}\right), \ldots$ Thus, if we substitute these expressions in the equation

$$2T = \Sigma\left[\theta\left(\frac{dT}{d\theta}\right)\right] = \Sigma\left[\theta\left(\frac{dA}{d\theta}\right)\right];$$

which is obviously true, because T is a homogeneous function of $\theta, \phi, \ldots$ of the second degree, we have a partial differential equation of the form

$$p\left(\frac{dA}{d\theta}\right)^2 + 2q\left(\frac{dA}{d\theta}\right)\left(\frac{dA}{d\phi}\right) + r\left(\frac{dA}{d\phi}\right)^2 + \ldots = 2(H - V),$$

from which A is to be found.

The coefficients $p, q, r \ldots$ are, in general, like P, Q, R, $\ldots$ functions of $\theta, \phi, \ldots$.

As an illustration, take again the example in last section, where two masses are attached to a helical spring, and vibrate in a vertical line. From the value of T there given we have

$$\left(\frac{dA}{d\xi}\right) = \left(\frac{dT}{d\dot{\xi}}\right) = (M+m)\dot{\xi} + m\dot{\eta},$$

$$\left(\frac{dA}{d\eta}\right) = \left(\frac{dT}{d\dot{\eta}}\right) = m\dot{\xi} + m\dot{\eta}.$$

From these we have the equation for A

$$m\left(\frac{dA}{d\xi}\right)^2 - 2m\left(\frac{dA}{d\xi}\right)\left(\frac{dA}{d\eta}\right) + (M+m)\left(\frac{dA}{d\eta}\right)^2 = 2Mm(H - V).$$

The value of V is given above. This equation is, of course, to be treated according to the process illustrated in § 209.

## Statics of a Rigid Solid.

Equilibrium of rigid solid.

§ 217. A rigid body, as we have already seen, has at the utmost six degrees of freedom, three of translation and three of rotation. According to Newton's scholium, the conditions of equilibrium of such a body, under the action of any system of forces, are that the algebraic sum of the rates of doing work by and against the forces shall be *nil* whatever uniform velocity of translation or of rotation the body may have. For, if this were not so, there would be work done against acceleration, and the body would gain or lose kinetic energy. And this gain or loss would take place even if the body were originally at rest, *i.e.*, it would not be in equilibrium. To ensure equilibrium then, all that is necessary is that the sums of the components of the forces in any three non-coplanar directions shall vanish, along with the sums of their moments about any three non-coplanar lines. For simplicity it is usual to assume for these directions a system of rectangular axes, and for the lines another system parallel to them and passing through some definite point (say the centre of inertia) of the body.

The six conditions.

Thus we have at once

$$\Sigma(X) = 0, \ \Sigma(Y) = 0, \ \Sigma(Z) = 0;$$

$$\Sigma(Zy - Yz) = 0, \ \Sigma(Xz - Zx) = 0, \ \Sigma(Yx - Xy) = 0,$$

where X, Y, Z are the components, parallel to the axes, of a force acting at the point $x, y, z$ of the body. If P, with direction cosines $\lambda, \mu, \nu$, represent the force acting at $x, y, z$, these equations may be written in the form

$$\Sigma(P\lambda) = 0, \ \Sigma(P\mu) = 0, \ \Sigma(P\nu) = 0$$

$$\Sigma[P(\nu y - \mu z)] = 0, \ \Sigma[P(\lambda z - \nu x)] = 0, \ \Sigma[P(\mu x - \lambda y)] = 0.$$

These equations correspond to the six degrees of freedom involved.

It is easy to see that it is a mere matter of convenience through what point of the body we draw the lines about which moments are taken. For, if we shift it by quantities $a, b, c$ respectively, the moments become

$$\Sigma\{Z(y - b) - Y(z - c)\}, \text{ &c.};$$

but these are $\Sigma(Zy - Yz) - b\Sigma(Z) + c\Sigma(Y)$ &c.;

and, by the first three equations, these quantities are seen to reduce themselves to their first terms. Hence, in forming the equations of equilibrium, simplicity will be gained by choosing as origin a point through which the line of action of one or more of the applied forces passes.

Again, the point of application of any one of the forces may be shifted at will anywhere along the line in which the force acts. For the equations of the line in which the force at $x, y, z$ acts are

$$\frac{x' - x}{X} = \frac{y' - y}{Y} = \frac{z' - z}{Z},$$

and these give $Zy' - Yz' = Zy - Yz$, &c.,

so that the expressions for the moments are unaltered if the point of application of the force be shifted to any position along the line in which it acts.

§ 218. In the great majority of treatises on Statics the fundamental propositions of the subject, above given, are deduced from the assumption (as a thing to be proved experimentally) of the result just established, which is designated the "principle of the transmission of force." Along with it are assumed the parallelogram of forces, and the principle of the "superposition of systems of forces in equilibrium." Since the publication of the *Principia*, the continued use of such methods must be looked upon as a retrograde step in science.

Couple.

§ 219. From this category we cannot quite except (so far at least as the usual modes of treating it are concerned) the valuable idea of the "couple," due to Poinsot. But the term is in such common use, and the idea in its applications sometimes of such importance, that it cannot be omitted here.

*A couple is a pair of equal forces acting on the same body in opposite directions and in parallel lines.*

From the general conditions already given we see that a couple produces a definite moment of force about a particular axis, but that the axis is determinate merely as regards direction, and not as regards position in space. The forces of a couple do not appear in the first three of the equations of equilibrium. On the other hand, the left hand members of the other three equations may all be regarded as moments of couples. All the properties of couples are contained in these statements. Thus, for instance, it is obvious that, so far as its effects are concerned—

Transference of couple.

1. A couple may be shifted by translation to any other position in its own plane.

2. It may be shifted to any parallel plane.

3. In either of these it may be turned through any angle.

Arm of couple.

4. Its forces may be increased or diminished in any ratio, provided the distance between their lines of action (which is called the "arm" of the couple) be proportionately diminished or increased.

Axis of couple.

A couple is therefore completely determined by means of its "axis," which is a line drawn perpendicular to its plane, and of length representing its moment. And two couples are obviously to be compounded by treating their axes as if they were forces acting at one point.

Reduction of a system to a force and a couple.

§ 220. We will now examine the consequences of the six conditions of equilibrium (§ 217) in some of the more common cases which present themselves. But, before doing so, it may make matters clearer if we restate these conditions in a somewhat different form.

*The resultant of any number of forces, acting at any points of a rigid body, may be represented by a single force acting at the origin, and a couple of definite moment about a definite line passing through the origin.*

*For equilibrium of the body this force and couple must separately vanish.*

Thus if, in fig. 59, P, acting at Q, be any one of the forces, and O the origin (chosen at random), we may introduce at O a pair of equal and opposite forces $\pm$ P, parallel to P. The original force, taken along with $-$ P at the origin, gives a couple; and in addition there is $+$ P acting at the origin.

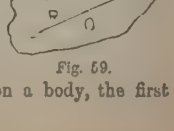

Fig. 59.

§ 221. When only two forces act on a body, the first

condition above shows that they must be equal and opposite, and the second that they must act in the same line, if they are to maintain equilibrium. When only three forces act, the first condition shows that their directions must lie in one plane, the second that their lines of action must be parallel or must meet in one point, if they are to maintain equilibrium.

If their directions meet in one point we have again the problem of the equilibrium of a single particle under three forces; for there can be no moment about this point.

When the directions are parallel, one of the forces must obviously be equal to the sum of the other two, and must act in the opposite direction. Also its line of action must lie between those of the other two, for their moments about any point in it must be equal and opposite. Hence it is impossible that any single force should balance a couple, unless we adopt the mathematical fiction of an infinitely small force acting in a line everywhere at an infinite distance; so that its moment may be finite, and equal and opposite to that of the couple.

Parallel forces.

§ 222. When any number of parallel forces act simultaneously on a rigid body, their resultant is a single force equal to their algebraic sum, with a couple whose plane is obviously parallel to the common direction of the forces. The forces of this couple may be made, by lengthening or shortening the arm, equal to the resultant force. One of them will neutralize it, and the other remains the final resultant, which passes through a definite point called the "centre of parallel forces." Thus any set of parallel forces necessarily has a single force as a resultant, excepting in the special case when their algebraic sum is zero.

"Centre."

Gravity.

§ 223. Excellent examples are furnished by heavy bodies of moderate dimensions, where the weights of their parts are forces practically in parallel lines. The single resultant force, in such cases, is the whole weight of the body. Its direction always passes through the centre of inertia (§ 109) because weight (in any one locality) is proportional to mass. For this reason all heavy bodies of moderate dimensions are said to have a "centre of gravity," which coincides with the centre of inertia. But it must be noticed that the two ideas are radically different, and that, while every piece of matter has a true centre of inertia, it is, in general, only approximately that we can predicate of it that it has a centre of gravity. In fact a body has a true centre of gravity only when it attracts, and is attracted by, all other gravitating matter as if its whole mass were concentrated in that point. See POTENTIAL. When there is a centre of gravity in a body, it is necessarily coincident with the centre of inertia. In gravitation cases, where bodies of moderate size are concerned, the resultant is, at least approximately, a single force. But, when we deal with large non-barycentric bodies like the earth, we find that the resultant of the sun's attraction is a force (determining the orbit) and a couple (producing precession, &c.).

Centre of gravity.

When a mass is laid on a three-legged table, we find the pressure which each leg supports by simply taking moments about the line joining the upper ends of the other two. The leg is thus seen to support a fraction of the weight of the mass, whose numerator is the distance of the centre of gravity of the mass from this line, and its denominator the distance of the leg from the same line. Thus we have a physical proof of the geometrical proposition that if any point, P, be taken in the plane of a triangle ABC (fig. 60), and perpendiculars be drawn from it and from the angles, we have

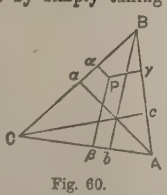

Fig. 60.

$$\frac{P\alpha}{Aa}+\frac{P\beta}{B\delta}+\frac{P\gamma}{Cc}=1.$$

If the mass of the table is to be reckoned, P must be taken as the centre of gravity of the system of table and load together. If the table be of uniform material, triangular, and supported by legs at its corners, similar reasoning shows that when it is unloaded (or loaded at its centre of gravity) each leg supports one third of the weight.

Resultant a couple.

§ 224. Examples in which the resultant is a single couple are found in rigidly magnetized bodies placed in a uniform magnetic field. As the amounts of N. and S. magnetism in a body are always equal, there is no force of translation in a uniform field. The resultant couple depends for its magnitude on the orientation of the body, and the positions of equilibrium are those for which its moment vanishes.

§ 225. Let P at $x, y, z$, be one of a system of parallel forces, their direction cosines being $\lambda, \mu, \nu$. Let Q be the resultant force, and R, with direction cosines $\lambda', \mu', \nu'$, the axis of the resultant couple. Then our conditions become

$$Q=\Sigma(P),$$

$$\lambda'R=\Sigma[P(\nu y-\mu z)],\quad \mu'R=\Sigma[P(\lambda z-\nu x)],\quad \nu'R=\Sigma[P(\mu x-\lambda y)].$$

The last three equations give the following conditions determining R, $\lambda', \mu', \nu'$:—

$$\begin{aligned}\lambda'R\quad &+\mu\Sigma(Pz)-\nu\Sigma(Py)=0,\\ -\lambda\Sigma(Pz)+\mu'R\quad &+\nu\Sigma(Px)=0,\\ +\lambda\Sigma(Py)-\mu\Sigma(Px)+\nu'R\quad &=0.\end{aligned}$$

From these we have the equation of condition

$$\lambda\lambda'+\mu\mu'+\nu\nu'=0,$$

showing that the axis of the couple is at right angles to the common direction of the parallel forces.

We have also

$$R^2=(\Sigma(Px))^2+(\Sigma(Py))^2+(\Sigma(Pz))^2-(\lambda\Sigma(Px)+\mu\Sigma(Py)+\nu\Sigma(Pz))^2.$$

This expression is of the same form as that in § 77, and we therefore conclude that, if $\lambda'', \mu'', \nu''$ be the direction cosines of a line in the body such that

$$\frac{\lambda''}{\Sigma(Px)}=\frac{\mu''}{\Sigma(Py)}=\frac{\nu''}{\Sigma(Pz)},$$

the magnitude of the resultant couple is directly as the sine of the angle between this line and the common direction of the parallel forces. In fact the mere form of the three equations above proves this result.

In the case of a body of moderate dimensions, acted on by gravity, P is the weight of the element at $x, y, z$, and therefore proportional to its mass, so that if the centre of inertia be taken as the origin we have

$$\Sigma(Px)=0,\quad \Sigma(Py)=0,\quad \Sigma(Pz)=0,$$

and there is no couple. The whole effect is therefore the same as if the mass were condensed at the centre of inertia.

In the case of a magnet,

$$\Sigma(P)=0,$$

and there is no translatory force. The couple, as we have seen, depends upon the orientation of the body as regards the direction of the line of the earth's magnetic force.

Reduction to two forces.

§ 226. We have seen that any system of forces acting on a rigid body may be reduced to a force and a couple; also that when the force is in the plane of the couple the resultant can always be put in the form of a single force acting in a definite line in the body. When the force is not in the plane of the couple, we may resolve the couple into two components, the plane of one being parallel, of the other perpendicular, to the force. The first, when compounded with the force, merely shifts the line in which it acts. Thus any system of forces may be reduced to a single force, acting in a definite line called the "central axis," and a couple in a plane perpendicular to it. One of the forces of the couple may now be compounded with the single force, and thus we obtain, as the resultant of any system of forces, a pair of forces in non-intersecting lines not perpendicular to one another. This is only one of an infinite number of ways in which fancy, or convenience, may lead us to represent the equivalent of a group of forces. Many very curious theorems have been met with in investigations on this subject. For instance, by compounding one of the forces of the resultant couple with the resultant force (not

Central axis.

now necessarily perpendicular to its plane) we have a system of two forces acting in non-intersecting lines. Then we have the following curious proposition, which may easily be proved from the formulæ already given:—

*When a system of forces is reduced in any manner whatever to two, the volume of the tetrahedron of which these are opposite edges is constant.*

Symmetrical reaction.

§ 227. The most symmetrical pair of resultant forces is found thus. Take any point P (fig. 61) in the central axis, and draw through it a line APA′, perpendicular to it, and bisected at P. Substitute for the single force at P its halves acting at A and A′ respectively. Combine these respectively with the forces AQ, A′Q′ of the couple when AA′ is made its arm. The system is thus reduced to two equal forces AR, A′R′, whose directions are interchangeable by a rotation of two right angles about the central axis.

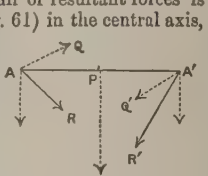

Fig. 61.

General reduction.

Let P with direction cosines $\lambda$, $\mu$, $\nu$ be one of the forces, and let $x$, $y$, $z$ be its point of application. Then

$$X=\Sigma(P\lambda),\quad Y=\Sigma(P\mu),\quad Z=\Sigma(P\nu)$$

are the components of the single force at the origin.

Also
$$L=\Sigma[P(\nu y-\mu z)]$$
$$M=\Sigma[P(\lambda z-\nu x)]$$
$$N=\Sigma[P(\mu x-\lambda y)]$$

are the components of the resultant couple.

If we shift the origin to the point $a$, $b$, $c$ the first three quantities are unaltered, but the couples become

$$L'=L+cY-bZ$$
$$M'=M+aZ-cX$$
$$N'=N+bX-aY.$$

The point $a$, $b$, $c$ is on the central axis if the axis of the resultant couple be parallel to the single force, *i.e.*, if

$$\frac{L'}{X}=\frac{M'}{Y}=\frac{N'}{Z}=e, \text{ suppose};$$

or
$$L=eX-cY+bZ,$$
$$M=cX+eY-aZ,$$
$$N=-bX+aY+eZ.$$

Either of these sets gives the equations of the central axis.

The resultant force and couple are in one plane, and therefore the resultant is a single force in the central axis, when

$$L'X+M'Y+N'Z=0.$$

By the values of L′, M′, N′, above, we see that this is equivalent

$$LX+MY+NZ=0.$$

When this last condition is not satisfied, we see that the value of the left hand member which, from the way in which it occurs, must obviously be an invariant, is

$$e(X^2+Y^2+Z^2),$$

where $e$ has the same value as in the three equations above.

Minding's theorem.

§ 228. One of the most remarkable of the many curious theorems connected with the single resultant of a system of forces is that of Minding. We have seen that, in general, the resultant may be put in the form of a single force and a couple in a plane perpendicular to it. If we now suppose the system of forces to be shifted into a new position such that their points of application, their magnitudes, and the angles between their directions two and two, all remain unchanged, the resultant force will be of the same magnitude as before, but the couple will in general be different. Of the infinitely infinite number of possible positions which the forces may assume, an infinite number correspond to a zero couple. Minding has shown that the lines of action of these single resultants consist of all lines passing through each of two curves, fixed in the body, an ellipse and an hyperbola, in planes perpendicular to each other. The proof of the proposition gives an interesting example of the use of Rodrigues's coordinates (§ 83).

The most obvious mode of attacking this question would be to resolve the applied forces into three groups, parallel respectively to three rectangular axes which revolve with them, and to choose those axes so that the sum of the resolved parts does not vanish parallel to any one of the three. Each of these systems of parallel forces has its own "centre" (§ 222),—so that the final resolution gives three forces, each of a given magnitude, acting in any mutually perpendicular directions at three definite points in the body. This, however, is not analytically so simple as the following.

We refer the body to fixed axes Ox, Oy, Oz, to be afterwards specified. As the origin and the directions of these axes are at our disposal, we may impose six conditions. Now suppose the forces to be resolved parallel to a set of rectangular axes Ox′, Oy′, Oz′ which will be considered afterwards to rotate with them. Such a system of axes may, at starting, have any assigned position. This gives us three conditions more. Let then A, B, C be the components, parallel to the second set of axes, of the force applied at the point whose coordinates referred to the first system are $a$, $b$, $c$. Let the direction cosines of the second system in any of its future positions, referred to the first system, be $l_1$, $m_1$, $n_1$; $l_2$, $m_2$, $n_2$; $l_3$, $m_3$, $n_3$ respectively.

Then the force at $a$, $b$, $c$ has the following components:—

$$Al_1+Bl_2+Cl_3,\quad \text{parallel to } Ox$$
$$Am_1+Bm_2+Cm_3,\quad \text{,,}\quad \text{,,}\ Oy$$
$$An_1+Bn_2+Cn_3,\quad \text{,,}\quad \text{,,}\ Oz.$$

The expressions for the resultant force and couple at the origin will evidently depend upon the following twelve quantities, besides the direction cosines, viz:—

$$\Sigma A,\quad \Sigma B,\quad \Sigma C,$$
$$\Sigma(Aa),\ \Sigma(Ab),\ \Sigma(Ac),$$
$$\Sigma(Ba),\ \Sigma(Bb),\ \Sigma(Bc),$$
$$\Sigma(Ca),\ \Sigma(Cb),\ \Sigma(Cc).$$

Assume $\Sigma B=0$, $\Sigma C=0$, *i.e.*, let Ox′ be always parallel to the direction of the resultant force. Next, let

$$\Sigma(Aa)=0,\ \Sigma(Ab)=0,\ \Sigma(Ac)=0,$$

*i.e.*, let the origin be chosen as the "centre" (§ 222) of the forces parallel to the resultant force. As we have still four conditions to impose, we select the following:—

$$\Sigma(Ba)=0,\ \Sigma(Bc)=0,\ \Sigma(Ca)=0,\ \Sigma(Cb)=0.$$

These express that the plane of the couple due to the forces C passes through Oy, while that of the forces B passes through Oz.

Write now

$$\Sigma(A)=\mathfrak{A},\ \Sigma(Bb)=\mathfrak{B}\beta,\ \Sigma(Cc)=\mathfrak{C}\gamma.$$

The force and couple at the origin are

$$\mathfrak{A}l_1,\quad \mathfrak{A}m_1,\quad \mathfrak{A}n_1,$$
$$\mathfrak{B}(n_2\beta-m_3\gamma),\quad \mathfrak{B}l_3\gamma,\quad -\mathfrak{B}l_2\beta.$$

These are equivalent to a single force if (§ 227)

$$(l_1n_2-n_1l_2)\beta-(l_1m_3-m_1l_3)\gamma=0,$$

or
$$m_3\beta-n_3\gamma=0 \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (1).$$

This is the required condition. When it is satisfied, the equations of the line in which the single force $\mathfrak{A}$ acts are any two of

$$\left.\begin{aligned} n_1\eta-m_1\zeta&=n_2\beta-m_3\gamma,\\ l_1\zeta-n_1\xi&=l_3\gamma,\\ m_1\xi-l_1\eta&=-l_2\beta \end{aligned}\right\} \quad . \quad . \quad . \quad . \quad . \quad (2),$$

the condition that these three agree being (1).

Eliminate $l_1$ between the last two, and we get

$$\xi(m_1\zeta-n_1\eta)=l_3\gamma\eta-l_2\beta\zeta \quad . \quad . \quad . \quad . \quad . \quad (3).$$

Now introduce in (1), in the first of (2), and in (3), Rodrigues's values of the cosines (§ 83), and they become respectively

$$(yz-wx)\beta-(yz+wx)\gamma=0,$$
$$(xz-wy)\eta-(wz+xy)\zeta=(yz+wx)\beta-(yz-wx)\gamma,$$
$$\zeta\xi(wz+xy)-\xi\eta(xz-wy)=(xz+wy)\gamma\eta-(xy-wz)\beta\zeta.$$

Rearranging according to $y$, $z$, and $yz$,

$$(\beta-\gamma)yz-(\beta+\gamma)wx=0,$$
$$(\beta-\gamma)yz+(w\eta+x\zeta)y-(x\eta-w\zeta)z+(\beta+\gamma)wx=0,$$
$$[\zeta(\xi+\beta)x+\eta(\xi-\gamma)w]y+[\zeta(\xi-\beta)w-\eta(\xi+\gamma)x]z=0,$$

the second of which may be put, by means of the first, in the form

$$(w\eta+x\zeta)y-(x\eta-w\zeta)z+2(\beta+\gamma)wx=0.$$

These three equations involve $w$, $x$, $y$, $z$ in the form of the ratios only of the last three to the first. The last two are linear in $\frac{y}{w}$, $\frac{z}{w}$. Solving them, and substituting in the first we find, finally, a biquadratic in $\frac{x}{w}$.

Hence, if particular values be assigned to $\xi, \eta, \zeta$, we find four values of $\frac{x}{w}$. Thus, in general, there are four positions of the single resultant force passing through any point.

But, without forming the biquadratic, we may easily obtain Minding's theorem. Suppose we seek the locus of all points in which the plane $\xi\eta$ can be cut by the line of action of the single force. We have $\zeta=0$, and the equations above are reduced to

$$(\beta-\gamma)yz-(\beta+\gamma)wx=0,$$
$$\eta(wy-xz)+2(\beta+\gamma)wx=0,$$
$$(\xi-\gamma)wy-(\xi+\gamma)xz=0.$$

From the last two we find

$$-\gamma\eta z=(\beta+\gamma)(\xi-\gamma)w,$$
$$-\gamma\eta y=(\beta+\gamma)(\xi+\gamma)x,$$

so that finally, by the first,

$$(\beta^2-\gamma^2)(\xi^2-\gamma^2)=\gamma^2\eta^2,$$

or

$$\frac{\xi^2}{\gamma^2}-\frac{\eta^2}{\beta^2-\gamma^2}=1 \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (4).$$

Had we put $v=0$, we should have found, by a similar process,

$$\frac{\xi^2}{\beta^2}+\frac{\zeta^2}{\beta^2-\gamma^2}=1 \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (5).$$

(4) and (5) represent an hyperbola and an ellipse, or an ellipse and an hyperbola, respectively, according as $\beta^2$ is greater or less than $\gamma^2$. In either case the vertices of the hyperbola coincide with the foci of the ellipse; so that the two curves are linked together.

It is now easy to see that, from any assigned point of space, the two curves will appear to intersect one another in four points. Two, or all, of these may in special cases coincide. Lines drawn to these points give the four positions of the single force which can pass through the assigned point.

*Examples of Statical Methods and Theorems.*

Ladder leaning against a wall.

§ 229. Suppose a ladder to be leaning against a vertical wall. If there be no friction, what force, applied at the lower end, will just suffice to support it?

In the treatment of all questions of this kind the student should commence by making a rough sketch of the situation, indicating all the forces concerned, with the directions in which they act. As shown in fig. 62, the wall exerts an outward thrust S on the upper end of the ladder, the ground an upward thrust R on the lower end. The only other force is gravity, which may be supposed to produce a downward force at the middle of the ladder, equal to its whole weight. Unless there be some other horizontal force to balance S, the ladder will obviously slide down. Suppose then a horizontal force F to be applied at the lower end, and let the ladder be inclined at an angle $\alpha$ to the horizon. Then our conditions become

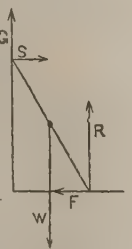

Fig. 62.

horizontally $S-F=0$,

vertically $W-R=0$,

and for the couple in the plane of the figure, $l$ being the length of the ladder,

$$\tfrac{1}{2}Wl\cos\alpha-Sl\sin\alpha=0.$$

[The last equation is obtained by taking moments about the lower end of the ladder, this point being chosen (§ 217) because the directions of two of the forces pass through it.] From these equations we find at once

$$F=S=\tfrac{1}{2}W\cot\alpha.$$

It is to be observed that the requisite force F is very small while the ladder is nearly vertical, but increases without limit as it becomes more nearly horizontal.

Use of friction.

§ 230. Next let us vary the question by supposing the coefficient of friction on the ground to be $\mu$. The equations are precisely the same as before, and the limiting value of $\alpha$ for which equilibrium is possible is now to be found by putting

$$F=\mu R=\mu W.$$

Thus

$$2\mu=\cot\alpha$$

gives the smallest value of $\alpha$ for which equilibrium is possible. For any larger value of $\alpha$ less friction is called into play.

§ 231. If next we assume the wall also to be rough, a new friction force, G, comes in. The equations (for any given value of $\alpha$) are

$$S-F=0,$$
$$W-R-G=0,$$
$$\tfrac{1}{2}Wl\cos\alpha-Sl\sin\alpha-Gl\cos\alpha=0.$$

Here there is a certain amount of indeterminateness which our formulæ cannot escape (although of course it does not exist in nature) so long as we are not dealing with the limiting case in which motion is about to commence. In that case we have the additional conditions

$$G=\mu S,\quad F=\mu R.$$

Thus, in all, there are five equations. These are requisite and necessary because there are four forces S, G, R, F to be determined, as well as the special value of the angle $\alpha$. The result of eliminating the four forces is

$$\tan\alpha=\frac{1-\mu^2}{2\mu}.$$

Man on ladder.

§ 232. We may still further vary the question by supposing a man of weight $w$ to ascend the ladder. Let $e$ represent the fraction of the ladder's length which he has ascended. The equations are

$$S-F=0,$$
$$W+w-R-G=0,$$
$$(\tfrac{1}{2}W+ew)l\cos\alpha_1-Sl\sin\alpha_1-Gl\cos\alpha_1=0.$$

Introducing the condition that slipping is just about to commence, we obtain

$$\frac{\tan\alpha_1}{\tan\alpha}=\frac{1+2\dfrac{w}{W}\dfrac{(1+\mu^2)e-\mu^2}{1-\mu^2}}{1+\dfrac{w}{W}}$$

where $\alpha$ has the value given in § 231. Hence the limiting angle is increased or diminished by the load on the ladder according as

$$2(1+\mu^2)e-2\mu^2\gtrless 1-\mu^2,$$

*i.e.*,

$$2e\gtrless 1.$$

The ratio $w/W$ does not appear in this condition. But it shows its importance when $e$ is either greater or less than $\frac{1}{2}$.

Hence, when the ladder is just about to slip, a man makes it more stable if he stands anywhere on the lower half of it, but brings it down if he mounts higher. We conclude that, so far as sliding is concerned, it is advantageous to make the lower half of a ladder more massive than the upper half.

§ 233. Suppose a ladder, with its lower end resting against a wall, to be supported by a horizontal rail parallel to the wall (fig. 63). This case is chosen because it illustrates definite limits within which stability is ensured.

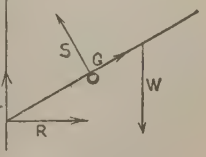

Fig. 63.

Let $a$ be the half length of the ladder, $\alpha$ its inclination to the horizon, $b$ the distance of the rail from the wall. Suppose the ladder in such a position that if there were no friction it would slip downwards. Then the equations of equilibrium are

$$R+G\cos\alpha-S\sin\alpha=0,$$
$$F+S\cos\alpha+G\sin\alpha-W=0,$$
$$Sb\sec\alpha-Wa\cos\alpha=0.$$

In the third of these equations the lower end of the ladder has been chosen as the point about which moments are taken, because the lines of action of three of the forces

pass through it. Here again there is indeterminateness, because there are two places at which friction comes in, and we do not know at which it is most freely exerted. But if the whole be on the point of slipping, we have as before the additional data

$$F=\mu R,\quad G=\mu S.$$

These lead to the equation

$$(1-\mu^2)\cos\alpha+2\mu\sin\alpha=\frac{b}{a}\sec^2\alpha\,.$$

If we introduce an angle $\nu$, such that

$$\cos\nu=\frac{1-\mu^2}{1+\mu^2},\quad \sin\nu=\frac{2\mu}{1+\mu^2}$$

this equation becomes

$$\cos^2\alpha\cos(\alpha-\nu)=\frac{b}{a(1+\mu^2)}=\frac{b}{a}\cos^2\frac{\nu}{2},$$

the right-hand member of which must necessarily be less than 1.

This determines the lowest position of the lower end consistent with equilibrium, and the mere change of sign of $\mu$, and therefore of $\nu$, alters it into the equation for the highest. The signs of the friction terms are changed when the direction of slipping is supposed to be reversed.

## Kinetics of a Rigid Solid.

Rotation of rigid solid.

§ 234. The motion of a rigid body is, as we have seen, completely determined when we know the motion of one of its points and the relative motion of the body about that point. The point usually chosen is the centre of inertia of the body, and the investigation of its motion comes under the kinetics of a particle, which we have already sufficiently discussed. For we are permitted to suppose the whole mass to be concentrated at that point, and to be acted on by all the separate forces, each unaltered in direction and magnitude. Hence we may now confine ourselves to the study of the motion about the centre of inertia which, for the moment, we may look on as fixed.

To illustrate, in a very simple manner, the new conceptions which are required for the study of this question, let us take a uniform circular ring of matter, of radius R, revolving with angular velocity $\omega$ about an axis through its centre, and perpendicular to its plane. Its moment of momentum is obviously

$$M\,.\,R\omega\,.\,R \text{ or } MR^2\,.\,\omega.$$

Its kinetic energy is

$$\tfrac{1}{2}M(R\omega)^2 \text{ or } \tfrac{1}{2}MR^2\,.\,\omega^2.$$

If it be acted on by a couple C, in its plane, C is the rate of increase of the moment of momentum, or

$$MR^2\,.\,\dot\omega=C.$$

The work done by the couple in time $\delta t$ is

$$C\omega\delta t,$$

and the increase of kinetic energy is

$$MR^2\,.\,\omega\dot\omega\delta t.$$

By equating these we have (after dividing both sides by $\omega$) the same equation as we obtained from the rate of increase of moment of momentum. It will be observed that these equations are of exactly the same form as those for the motion of a particle parallel to one of the coordinate axes, only that $\omega$ takes the place of a velocity (such as $\dot x$) while the expression $MR^2$ takes the place of M, and the right-hand side is the moment of a force, not a force simply.

Moment of inertia.

§ 235. Hence, generally, we define as follows:—

Def. The "moment of inertia" of a body about any axis is the sum of the products of the mass of each particle of the body into the square of its (least) distance from the axis.

The following theorem enables us at once to find the moment of inertia about any line, as axis, from that about a parallel axis through the centre of inertia.

Let the line be chosen as the axis of $z$, then the moment of inertia about it is

$$\Sigma m(x^2+y^2).$$

But, if $\bar x$, $\bar y$ be the coordinates of the centre of inertia, $\xi$, $\eta$ the coordinates of $m$ with reference to that centre, we have

$$x=\bar x+\xi\,,\ y=\bar y+\eta\,,$$

and the above expression for the moment of inertia becomes

$$\Sigma m(\bar x^2+\bar y^2+2\bar x\xi+2\bar y\eta+\xi^2+\eta^2).$$

By the property of the centre of inertia, § 109,

$$\Sigma(m\xi)=0\,,\ \Sigma(m\eta)=0\,.$$

Hence the above expression consists of two parts:—

$$\Sigma m(\xi^2+\eta^2)$$

the moment of inertia about a parallel axis through the centre of inertia, and

$$\Sigma(m)\,.\,(\bar x^2+\bar y^2)$$

the moment of inertia of the whole mass supposed concentrated at its centre of inertia.

§ 236. Hence we need study only the moments of inertia about axes passing through the centre of inertia. But we will commence with an origin assumed at hazard.

If the direction cosines of an axis through the origin be $\lambda$, $\mu$, $\nu$, the square of the distance of the mass $m$ at $x$, $y$, $z$ from it is

$$x^2+y^2+z^2-(\lambda x+\mu y+\nu z)^2$$

Hence the moment of inertia is

$$\mathfrak{I}=\Sigma m(x^2+y^2+z^2-(\lambda x+\mu y+\nu z)^2)$$
$$=\Sigma m((y^2+z^2)\lambda^2+(z^2+x^2)\mu^2+(x^2+y^2)\nu^2-2xy\lambda\mu-2yz\mu\nu-2zx\nu\lambda)),$$

which may be written

$$\mathfrak{I}=A\lambda^2+2G_3\lambda\mu+B\mu^2+2G_1\mu\nu+2G_2\nu\lambda+C\nu^2\,.$$

If we measure off, on the axis, a quantity $\rho$ whose square is the reciprocal of $\mathfrak{I}$, and call its terminal coordinates $\xi$, $\eta$, $\zeta$, this equation becomes by multiplying both sides by $\rho^2$

$$1=A\xi^2+2G_3\xi\eta+B\eta^2+2G_1\eta\zeta+2G_2\zeta\xi+C\zeta^2.$$

As the moment of inertia is essentially a positive quantity, this equation represents an ellipsoid. It must of course have three principal axes; and, when these are taken as the coordinates axes, the terms in $\xi\eta$, $\eta\zeta$, and $\zeta\xi$ in the above expression must disappear.

Principal axes of inertia.

§ 237. Hence at every point of every rigid body there are three "principal axes" of inertia, at right angles to one another. One of them is the axis of absolute maximum moment, another that of absolute minimum.

Our equation now becomes, when referred to these axes,

$$1=A\xi^2+B\eta^2+C\zeta^2,$$

or, dividing by $\rho^2$,

$$\mathfrak{I}=A\lambda^2+B\mu^2+C\nu^2.$$

Thus the moment of inertia about any axis is found from those about the principal axes at that point by multiplying each by the square of the corresponding direction cosine, and adding the results.

For the quantity A was written originally as

$$\Sigma m(y^2+z^2),$$

*i.e.*, it is the moment of inertia about the axis of $x$. We see also that, at every point of a body, there are three rectangular axes such that the expressions

$$\Sigma(mxy),\ \Sigma(myz),\ \Sigma(mzx)$$

vanish when these are taken as coordinate axes.

Distribution of the principal axes. Radius of gyration.

To find how these axes are distributed in a body, let us suppose it referred to the principal axes through its centre of inertia, and let $Mk_1^2$, $Mk_2^2$, $Mk_3^2$ be the moments of inertia about them. The quantities $k_1$, $k_2$, $k_3$ are called the principal "radii of gyration." Then, by the results above, the moment of inertia about a line $\lambda$, $\mu$, $\nu$ through the point $\alpha$, $\beta$, $\gamma$ is

$$\mathfrak{I}=M\{\alpha^2+\beta^2+\gamma^2-(\lambda\alpha+\mu\beta+\nu\gamma)^2\}+M(\lambda^2k_1^2+\mu^2k_2^2+\nu^2k_3^2).$$

For a principal axis this is to be a maximum or minimum, with the sole condition

$$\lambda^2+\mu^2+\nu^2=1\,.$$

Hence, if $p$ be an undetermined multiplier, we have

$$(k_1^2+p)\lambda-\alpha(\alpha\lambda+\beta\mu+\gamma\nu)=0,$$
$$(k_2^2+p)\mu-\beta(\alpha\lambda+\beta\mu+\gamma\nu)=0,$$
$$(k_3^2+p)\nu-\gamma(\alpha\lambda+\beta\mu+\gamma\nu)=0.$$

But, if we consider a surface of the second order

$$\frac{x^2}{k_1^2+p}+\frac{y^2}{k_2^2+p}+\frac{z^2}{k_3^2+p}=1,$$

confocal with the ellipsoid

$$\frac{x^2}{k_1^2}+\frac{y^2}{k_2^2}+\frac{z^2}{k_3^2}=1, \quad \ldots\ldots\ldots \quad (a),$$

the direction cosines of its normal at $x, y, z$ are

$$\lambda:\mu:\nu::\frac{x}{k_1^2+p}:\frac{y}{k_2^2+p}:\frac{z}{k_3^2+p}.$$

Hence, if this surface pass through the point $\alpha, \beta, \gamma$, we have

$$(k_1^2+p)\lambda=\mathrm{P}\alpha,$$
$$(k_2^2+p)\mu=\mathrm{P}\beta,$$
$$(k_3^2+p)\nu=\mathrm{P}\gamma,$$

where P is determined by the equation

$$\alpha\lambda+\beta\mu+\gamma\nu=\mathrm{P}\left(\frac{\alpha^2}{k_1^2+p}+\frac{\beta^2}{k_2^2+p}+\frac{\gamma^2}{k_3^2+p}\right)=\mathrm{P}.$$

Substitute this value of P in the preceding equations, and they become identical with those above given for determining the principal axes at $\alpha, \beta, \gamma$. Hence Binet's Theorem :—

*The principal axes at any point of a body are normals to the three surfaces of the second order which pass through that point and are confocal with the ellipsoid* $(a)$.

Principal moments of inertia.

§ 238. We will here tabulate the values of the moments of inertia about principal axes through the centre of inertia, in a few specially useful cases.

1. Plane uniform circular disk.

Divide it into concentric rings, of radius $r$, of breadth $\delta r$. Then the moment of inertia about the axis through the centre, and perpendicular to the plane, of the circle is

$$\rho\int_0^a 2\pi r^3 dr=\tfrac{1}{2}\pi a^4\rho,$$

where $a$ is the radius, and $\rho$ the mass of a square unit, of the disk. But the mass is $\pi a^2\rho$,

so that $$k_3^2=\tfrac{1}{2}a^2.$$

This of course, applies to a circular cylinder. Obviously, in the disk

$$k_2^2=k_3^2=\tfrac{1}{2}k_1^2=\tfrac{1}{4}a^2.$$

In fact the moment of inertia about an axis drawn perpendicular to any plane figure at any point is equal to the sum of the other two about rectangular axes which lie in the plane. The one is $\Sigma m(x^2+y^2)$, and the others are $\Sigma mx^2$ and $\Sigma my^2$ respectively.

2. Uniform rod of length $l$, $\rho$ mass per unit length.

$$\mathrm{M}=l\rho, \quad \mathrm{M}k_1^2=0, \quad \mathrm{M}k_2^2=\mathrm{M}k_3^2=2\rho\int_0^{\frac{1}{2}l}x^2dx=\frac{\rho l^3}{12};$$

so that $$k_2^2=k_3^2=\tfrac{1}{12}l^2.$$

3. Uniform rectangular plate, sides $a$ and $b$, axis parallel to $b$.

$$\mathrm{M}k^2=2b\rho\int_0^{\frac{a}{2}}x^2dx=\frac{a^3b}{12}\rho,$$

so that $$k_1^2=\tfrac{1}{12}a^2, \text{ and } k_2^2=\tfrac{1}{12}b.$$

Hence, by the remark above,

$$k_3^2=\tfrac{1}{12}(a^2+b^2).$$

4. Uniform sphere, radius $a$, $\rho$ mass per unit volume. Here

$$\Sigma(mx^2)=\Sigma(my^2)=\Sigma(mz^2),$$

and therefore the sum of any two is

$$=\tfrac{2}{3}\Sigma m(x^2+y^2+z^2).$$

Thus $$\mathrm{M}k_1^2+\mathrm{M}k_2^2=\mathrm{M}k_3^2=\tfrac{2}{3}4\pi\rho\int_0^a r^4dr=\tfrac{8}{15}\pi\rho a^5.$$

But $$\mathrm{M}=\tfrac{4}{3}\pi\rho a^3,$$

and thus $$k_1^2=k_2^2=k_3^2=\tfrac{2}{5}a^2.$$

5. Plane uniform elliptic disk, semiaxes $a, b$; $\rho$ mass of unit area. Moment of inertia about $a$ is

$$\mathrm{M}k_1^2=2\rho\int_0^a\frac{y^3}{3}dx=\frac{\pi ab^3\rho}{4}$$

so that $$k_1^2=\tfrac{1}{4}b^2.$$

From this follows immediately

6. Ellipsoid, semiaxes $a, b, c$, and of uniform density :—

$$k_1^2=\tfrac{1}{5}(b^2+c^2), \quad k_2^2=\tfrac{1}{5}(c^2+a^2), \quad k_3^2=\tfrac{1}{5}(a^2+b^2).$$

From these we can, of course, reproduce the result for a sphere.

7. Rectangular parallelepiped, edges $a, b, c$ :—

$$k_1^2=\tfrac{1}{12}(b^2+c^2), \quad k_2^2=\tfrac{1}{12}(c^2+a^2), \quad k_3^2=\tfrac{1}{12}(a^2+b^2).$$

The determination of moments of inertia is, like that of centres of inertia, a purely mathematical matter, the full discussion of which would lead us away from the proper objects of this article.

Rotation about fixed axis.

§ 239. The simplest cases that can present themselves so far as rotation is concerned (for the translational effects on a rigid body are treated precisely as if it were a mere particle,—a process already sufficiently illustrated) are those in which there is one degree of freedom to rotate, *i.e.*, when the body is rigidly attached to a fixed axis. Here the physical condition is simply that the rate of increase of moment of momentum is equal to the moment of the resultant couple about the axis of rotation.

Pulley of Atwood's machine.

§ 240. Let us recur to Atwood's machine as a first example, and suppose the string not to slip on the pulley, so that the pulley must turn. In this case we must observe that the two free parts of the string are now, as it were, separate strings, so that we have no right to assume their tensions to be equal. In fact if they were equal there would be no acceleration of the rotation of the pulley, nor of course of the common velocity of the two masses. We assume that the pulley is symmetrical, and the axis through its centre of inertia.

Let $a$ be the radius of the pulley, and $\omega$ its angular velocity, then $a\omega$ is the linear velocity of either mass. Thus the linear acceleration of each of the masses is equal to $a$ times the angular acceleration of the pulley. But the linear acceleration multiplied by the mass is the measure of the force producing it; while the angular acceleration multiplied by the moment of inertia is the measure of the moment of the couple producing it. Thus we have (M being the mass of the pulley, and $k$ its radius of gyration)

$$\mathrm{M}k^2\times\text{angular acceleration}=(\mathrm{T}'-\mathrm{T})a,$$
$$m'\times\text{linear acceleration}=m'g-\mathrm{T}',$$
$$m\times\text{linear acceleration}=\mathrm{T}-mg.$$

Eliminating T and T', and taking account of the above relation between the accelerations, we find at once

$$\text{Linear Acceleration}=\frac{m'-m}{m'+m+\mathrm{M}k^2/a^2}g;$$

from which, by the last two of our equations, the separate values of T and T' may be found.

If we compare this result with that obtained in § 173, on the supposition that the pulley was perfectly smooth, we see that the only difference is in the addition of $\mathrm{M}k^2/a^2$ to the sum of the two masses. Otherwise the nature of the motion remains unaffected.

Compound pendulum.

§ 241. Let us next take the case of a body of any form attached to a horizontal axis which does not pass through its centre of inertia. In such a case gravity is the force producing motion, and we have what is called a "compound pendulum." Draw through the centre of inertia a line parallel to the axis; let $h$ be the distance between these lines, and $\theta$ the angle which their plane makes (at a given time) with the vertical. The moment producing angular acceleration is obviously

$$-mgh\sin\theta.$$

Divide by the moment of inertia about the axis, which by a previous proposition (§ 235) is

$$m(k^2+h^2)$$

(where $k$ is the radius of gyration about the line drawn through the centre of inertia), and we have for the angular acceleration

$$-\frac{gh\sin\theta}{k^2+h^2}.$$

In the case of a simple pendulum of length $l$, we saw that the angular acceleration is

$$-\frac{g\sin\theta}{l}$$

Hence the motion of the compound pendulum will be identical with that of the simple pendulum when, and only when,

$$l=\frac{k^2+h^2}{h}=2k+\frac{(k-h)^2}{h}$$

As $h$ and $k$ are necessarily positive (or rather *signless*) quantities, the smallest value of $l$ is evidently when $k=h$. Hence the shortest time in which the mass can vibrate about any axis parallel to the original one corresponds to that of a simple pendulum of length $2k$. When $h$ is made either less or greater than $k$, the length of the equivalent simple pendulum increases, and for any assigned value of $l$ greater than $2k$ there are two corresponding values of $h$, one less and the other greater than $k$. Their sum, however, as we see by the coefficient of the second term in the equation

$$h^2-lh+k^2=0,$$

is always equal to $l$.

If then we can find two parallel axes in a rigid body, lying in one plane with the centre of inertia, and on opposite sides of that point, such that the time of oscillation is the same for each, the distance between them is the length of the equivalent simple pendulum. Kater made use of this proposition in his determination of the length of the second's pendulum, under the circumstances in which it was defined by Act of Parliament as a datum for restoring, in case of loss, the standard yard.

Complex compound pendulum.

§ 242. Suppose now that a second body is attached to the first by an axis parallel to that about which the first is constrained to move; and, for simplicity, suppose the centre of inertia of the first body to be in the plane containing the two axes. Here we have a *complex compound pendulum*, and it is interesting to compare the motion with that of the complex simple pendulum of §§ 177, 178.

Let $m'$, $h'$, $\phi$ correspond, for the second body, to $m$, $h$, $\theta$ for the first, and let $a$ be the distance between the axes. For variety we will adopt Lagrange's method. We have clearly

$$T=\tfrac{1}{2}\left(mk^2\dot\theta^2+mh^2\dot\theta^2+m'k'^2\dot\phi^2+m'(a^2\dot\theta^2+h'^2\dot\phi^2+2ah'\cos(\phi-\theta)\dot\phi\dot\theta\right),$$
$$V=C-mgh\cos\theta-m'g(a\cos\theta+h'\cos\phi).$$

These would enable us at once to write down the equations of motion, however large be the disturbance, but they are too complex for our present work. Let us then assume $\phi$ and $\theta$ to be very small, and we have

$$\left\{m(k^2+h^2)+m'a^2\right\}\ddot\theta+m'ah'\ddot\phi=-(mh+m'a)g\theta,$$
$$m'(k'^2+h'^2)\ddot\phi+m'ah'\ddot\theta=-m'gh'\phi.$$

Combining, as before, by means of an undetermined multiplier, we have

$$(m(k^2+h^2)+m'a^2+\lambda m'ah')\ddot\theta+(m'ah'+\lambda m'(k'^2+h'^2))\ddot\phi$$
$$=-g\left\{(mh+m'a)\theta+\lambda m'h'\phi\right\}.$$

Thus the two values of $\lambda$ are given by the equation

$$\frac{m'ah'+\lambda m'(k'^2+h'^2)}{m(k^2+h^2)+m'a^2+\lambda m'ah'}=\frac{\lambda m'h'}{mh+m'a}.$$

This may be written in the form

$$\frac{A+\lambda}{B+\lambda}=\frac{\lambda}{C},$$

where B is greater than A; and A, B, C are all essentially positive, if the bodies have been only slightly displaced from the position of stable equilibrium. The equation gives

$$\lambda^2+(B-C)\lambda-AC=0,$$

so that the values of $\lambda$ are essentially real and of opposite signs. If we write $\mu-B$ for $\lambda$, this equation becomes

$$\mu^2-(B+C)\mu+(B-A)C=0,$$

so that the values of $\lambda+B$ are both positive, and therefore the motion of either mass is the resultant of two simple harmonic motions.

§ 243. A well-known puzzle in connexion with this subject used to be "How to distinguish between two hollow shells, one of gold the other of silver, if their diameters and masses be alike, and both be painted." If we observe that the volumes of equal masses are inversely as the densities, the volume of the gold shell is seen to be less than that of the silver one, and therefore, on the whole, its mass is farther from the centre, and its moment of inertia greater. Hence any form of experiment in which the moment of inertia comes in will suffice to decide the question. Thus they might be alternately clamped tight to the end of a rod, and the system swung as a pendulum, when the gold sphere would vibrate more slowly than the silver one. Or they might be allowed to *roll*, not *slide*, down a rough plane. In this case the work done by gravity on each is the same when they have fallen through equal spaces. But its equivalent is in the form of kinetic energy, partly translational and partly rotational. The relative amounts of these two depend on the moments of inertia of the spheres, for the ratio of the translational velocity to the angular velocity is the same for each. Hence the gold sphere, having the greater moment of inertia, will have the smaller velocity of translation. Another form of this question was to have a shell with a spherical mass inside, which might be either free to rotate on gimbals, or else be keyed to the outer skin. The keying would of course retard the motion of the whole down a rough plane, for part of the energy due to gravity would then be shared by the internal mass in the form of energy of rotation, from which it would otherwise have been free. Another very instructive form is that of a spherical shell full of fluid. If the fluid be perfect, the moment of inertia is that of the shell alone; if it be infinitely viscous, the moment of inertia is that of shell and fluid as if they constituted one rigid solid; and we may have every intermediate amount. If we suppose the rotation of the outer shell to be suddenly stopped, the infinitely viscous contents would be reduced to rest also. But if they be not infinitely viscous they will not at once be brought to rest, but will be able to put the shell in rotation again if it be at once set free. Thus, in practice, we can tell a raw egg from a hard-boiled egg. The first is with difficulty made to rotate, and sets itself in motion again if it be stopped and at once let go. The second behaves, practically, like a rigid solid.

Rolling of hollow shells.

§ 244. The problem of the rolling of a sphere down a rough inclined plane is solved at once, as above, by applying the conservation of energy. For, if $x$ be the coordinate of its centre parallel to the plane, $\theta$ the angle through which it has turned, and $a$ its radius, we have the kinematical condition

$$x=a\theta$$

(due to the perfect roughness of the plane).

Also the potential energy lost is

$$Mgx\sin\alpha,$$

where $\alpha$ is the inclination of the plane to the horizon; and the kinetic energy gained is made up of the two parts,—$\frac{1}{2}M\dot x^2$ translational, and $\frac{1}{2}Mk^2\dot\theta^2$ rotational.

Hence
$$M(k^2+a^2)\dot\theta^2=2Mga\theta\sin\alpha,$$

or
$$\ddot x^2=2\frac{a^2g}{k^2+a^2}x\sin\alpha$$

This shows that the motion is the same as that of a particle sliding down a *smooth* plane of the same inclination, under gravity diminished in the ratio $a^2:k^2+a^2$. And it shows how friction may retard motion without producing any dissipation of energy.

§ 245. Suppose one point of a rigid plane sheet be made to move in any manner in the plane of the sheet, what will be the consequent rotation?

Let M be the mass, and $\xi$, $\eta$, given in terms of $t$, the coordinates

Varying constraint of one point of a body.

of the point of the sheet whose motion is assigned. Let $a$, $\theta$ be the relative polar coordinates of the centre of inertia, then

$$M[\ddot{\xi}+a(\cos\theta)]=X, \quad M[\ddot{\eta}+a(\sin\theta)]=Y,$$
$$Mk^2\ddot{\theta}=-Ya\cos\theta+Xa\sin\theta;$$

where X and Y are the forces requisite to produce the motion. Eliminating them, we find

$$(k^2+a^2)\ddot{\theta}=-a(\ddot{\eta}\cos\theta-\ddot{\xi}\sin\theta),$$

with which we can do no more until further data are specified.

Suppose $\xi$, $\eta$ to move with uniform acceleration $p$ in a direction assigned by $\alpha$, then

$$\ddot{\xi}=p\cos\alpha, \quad \ddot{\eta}=p\sin\alpha, \text{ and}$$
$$(k^2+a^2)\ddot{\theta}=-ap(\sin\alpha\cos\theta-\cos\alpha\sin\theta)=ap\sin(\theta-\alpha).$$

The centre of inertia of the mass therefore moves, relatively to the constrained point, precisely as does a simple pendulum; but the direction of $p$ is reversed.

Again suppose the constrained point to move uniformly in a circle of radius $b$, with angular velocity $\omega$. We have

$$\xi=b\cos\omega t, \quad \eta=b\sin\omega t,$$

and
$$(k^2+a^2)\ddot{\theta}=+\omega^2ab(\sin\omega t\cos\theta-\cos\omega t\sin\theta),$$

or
$$(k^2+a^2)\left(\frac{d}{dt}\right)^2(\theta-\omega t)=-\omega^2ab\sin(\theta-\omega t).$$

This is, again, the equation of motion of a simple pendulum, but the angle of displacement $\theta-\omega t$ is no longer measured from a fixed line but from the uniformly rotating radius of the guide circle. Hence the mass oscillates, pendulum-wise, about this uniformly revolving line.

Ballistic pendulum.

§ 246. Let us take, as an instance of impulse, the case of Robins's "ballistic pendulum,"—a massive block of wood movable about a horizontal axis at a considerable distance above it,—employed to measure the velocity of a cannon or musket shot. The shot is usually fired into the block in a horizontal direction perpendicular to the axis. The impulsive penetration is so nearly instantaneous, and the mass of the block so large compared with that of the shot, that the ball and pendulum are moving on as one mass before the pendulum has been sensibly deflected from the position of equilibrium. This is the essential peculiarity of the ballistic method,—which is used also extensively in electromagnetic researches and in practical electric testing, when the integral quantity of the electricity which has passed in a current of short duration is to be measured. The line of motion of the bullet at impact may be in any direction whatever, but the only part which is effective is the component in a plane perpendicular to the axis. We may therefore, for simplicity, consider the motion to be in a line perpendicular to the axis, though not necessarily horizontal.

Let $m$ be the mass of the bullet, $v$ its velocity, and $p$ the distance of its line of motion from the axis. Let M be the mass of the pendulum with the bullet lodged in it, and $k$ its radius of gyration. Then, if $\omega$ be the angular velocity of the pendulum when the impact is complete,

$$mvp=Mk^2\omega,$$

from which the solution of the question is easily determined. For the kinetic energy after impact is changed into its equivalent in potential energy when the pendulum reaches its position of greatest deflexion. Let this be given by the angle $\theta$; then the height to which the centre of inertia is raised is $h(1-\cos\theta)$, if $h$ be its distance from the axis. Thus

$$Mgh(1-\cos\theta)=\tfrac{1}{2}Mk^2\omega^2=\tfrac{1}{2}\frac{m^2v^2p^2}{Mk^2},$$

or
$$2\sin\frac{\theta}{2}=\frac{m}{M}\frac{p}{k}\frac{v}{\sqrt{gh}},$$

an expression for the chord of the angle of deflexion. In practice the chord of the angle $\theta$ is measured by means of a light tape or cord attached to a point of the pendulum, and slipping with small friction through a clip fixed close to the position occupied by that point when the pendulum hangs at rest.

§ 247. As another example of impulse let us consider the case of a body moving in any way in a plane perpendicular to one of its principal axes. It is required to find what point of the body must be suddenly fixed in order that the whole may be brought to rest; also, what will be the consequent impulsive pressure at this point. It is easy to see that this is exactly the same question as to find the impulse, and its point of application, so that it may produce a given motion of a body in a plane perpendicular to one of its principal axes.

Impulse required for a given motion.

The impulse must obviously act in a plane passing through the centre of inertia. And the physical conditions are that the change of momentum of translation is equal to, and in the direction of, the impulse, while the change of moment of momentum about the centre of inertia is equal to the moment of the impulse. Let the impulse acting at the point $\xi$, $\eta$ have components R, S parallel to rectangular coordinates in the plane of motion, and let $\omega$ be the angular velocity, $u$, $v$ the linear velocities, generated by it. Then the physical conditions are

$$Mu=R, \quad Mv=S, \quad Mk^2\omega=S\xi-R\eta.$$

When $u$, $v$, $\omega$ are given, R and S are found from the first two equations, and the third is then the equation of the line in which the impulse must act. Similarly, when the impulse and its line of action are given, we have in terms of these data the quantities $u$, $v$, $\omega$.

Centre of percussion.

§ 248. As a simple practical example, suppose one strikes a hard object with a stick in such a way that his hand is at rest at the instant of the impact; with what part of the stick must he strike so that there may be no jar on his hand?

Let $\xi$ be measured along the stick from its centre of inertia in the direction which it has at the instant of impact. Then the kinematical condition is

$$v=a\omega,$$

where $a$ is the distance from the hand to the centre of inertia of the stick. Thus, as the impulse S is the sole cause of the stick's being brought to rest, we have

$$Mv+S=0, \quad Mk^2v/a+S\xi=0;$$

so that
$$\xi=k^2/a.$$

Hence if the stick be uniform and be held by one end, so that its length is $2a$, and therefore $3k^2=a^2$, we have

$$\xi=\tfrac{2}{3}a;$$

and $a+\xi$, the distance of the point of impact from the hand, is

$$a+\tfrac{2}{3}a=\tfrac{2}{3}.2a,$$

*i.e.*, it is at two-thirds of the length of the stick.

If, however, the hand be moving, at the instant of impact, perpendicularly to the stick with velocity V, the kinematical condition is $v-V=a\omega$, which introduces a corresponding change in the result.

Reaction on axis.

§ 249. The reaction of the axis is easily calculated. If the axis about which the body is constrained to rotate be perpendicular to a plane though the centre of inertia about which the body is symmetrical, and if the applied forces act in that plane, it is clear that the reaction of the axis is a single force in that plane. Let its components be $\Xi$ and H. Then

$$\Sigma(m\ddot{x})=\Sigma(X)+\Xi, \quad \Sigma(m\ddot{y})=\Sigma(Y)+H,$$
$$\Sigma m(x\ddot{y}-y\ddot{x})=\Sigma(xY-yX).$$

Let $a$, $\theta$, be the polar coordinates of the centre of inertia, then $\dot{\theta}$, $\ddot{\theta}$ are the angular velocity and the angular acceleration for all particles of the mass, and we have

$$-Ma\cos\theta.\dot{\theta}^2-Ma\sin\theta.\ddot{\theta}=\Sigma(X)+\Xi,$$
$$-Ma\sin\theta.\dot{\theta}^2+Ma\cos\theta.\ddot{\theta}=\Sigma(Y)+H,$$
$$M(k^2+a^2)\ddot{\theta}=\Sigma(xY-yX).$$

From the third we find $\theta$, and the others give $\Xi$ and H.

When there is no plane of symmetry perpendicular to the axis, there must be two points of it at which reactions are exerted on the revolving body. Let the coordinates of these bearings be $c$, $c'$, and the reactions there $\Xi$, H, Z, $\Xi'$, H', Z' respectively.

Then we have the six equations (in which $\ddot{z}=0$)

$$\Sigma(m\ddot{x})=\Sigma(X)+\Xi+\Xi',$$
$$\Sigma(m\ddot{y})=\Sigma(Y)+H+H',$$
$$\Sigma(m\ddot{z})=\Sigma(Z)+Z+Z';$$
$$\Sigma m(x\ddot{y}-y\ddot{x})=\Sigma(xY-yX),$$
$$\Sigma m(y\ddot{z}-z\ddot{y})=\Sigma(yZ-zY)-cH-c'H',$$
$$\Sigma m(z\ddot{x}-x\ddot{z})=\Sigma(zX-xZ)+c\Xi+c'\Xi'.$$

The fourth equation, as before, determines $\theta$, and we have then four equations to determine $\Xi$, $\Xi'$, H, H'. The remaining equation determines only the sum $Z+Z'$. In fact by more or less perfect *fitting* we can throw more or less of the force parallel to the axis on one or other of the bearings. There is really no indeterminateness in nature, but we cannot get the information required to evaluate separately Z and Z'.

§ 250. When impulsive forces are applied to the body, exactly the same methods may be employed, with the exception that $u'-u$ must be written for $\dot{x}$, &c., and $\omega'-\omega$ for $\ddot{\theta}$. The quantities X, Y, Z, $\Xi$, H, Z, $\Xi'$, H', Z' now denote impulses and not forces.

As a single example of the use of these formulæ, take the case of a body rotating, under the action of no force, about an axis through its centre of inertia. Here $\Sigma(mx)=0$, &c., and $z$ is constant. The first two of the six equations last written show that the pairs of forces $\Xi$, $\Xi'$ and H, H' form couples. The fourth equation gives $\theta=\omega t$; and with this the remaining two become

$$\Sigma(mzy).\omega^2=-cH-c'H'=-(c-c')H,$$
$$\Sigma(mzx).\omega^2=-c\Xi-c'\Xi'=-(c-c')\Xi.$$

The multipliers of $\omega^2$ are each zero if the axis of rotation be a principal axis, and thus, in this case, there is no stress perpendicular to the axis. When the axis is not a principal axis the left hand terms are generally finite but they vary as the body turns. It is easy to see, however, that together these terms constitute a constant couple always in a plane passing through the axis, rotating with the body and dependent directly on the square of the angular velocity. Thus, to analyse the factor $\Sigma(mzy)$, we note that $z$ is constant, and

$$y=r\sin(\omega t+\alpha),$$

where $r$, $\alpha$ were the polar coordinates of the mass $m$ at time $t=0$.

Hence $$\Sigma(mzy)=\sin\omega t\,\Sigma(mzx_1)+\cos\omega t\,\Sigma(mzy_1),$$

where $x_1=r\cos\alpha$ and $y_1=r\sin\alpha$ were the coordinates of $m$ at $t=0$.

Similarly we have

$$\Sigma(mzx)=\cos\omega t\,\Sigma(mzx_1)-\sin\omega t\,\Sigma(mzy_1).$$

These expressions prove the preceding statements.

One point suddenly stopped.

§ 251. As a final instance of impulse in this branch of the subject, suppose that a rigid plate, moving anyhow in its own plane, has one of its points suddenly fixed, what will be the subsequent motion? Let the position in space at which the point is to be fixed be chosen as origin, and let the axis of $x$ be chosen so as to pass through the centre of inertia at the moment of fixture. Then, if $u$, $v$ be the velocities of the centre of inertia, $\omega$ the angular velocity about it, $a$ its distance from the point to be fixed, the conditions of the impact are

$$u'=u-\Xi/M,$$
$$v'=v-H/M,$$
$$\omega'=\omega+Ha/Mk^2,$$

—three equations with five unknown quantities. But the conditions that the point in question is reduced to rest are evidently

$$u'=0,\quad v'-\omega'a=0.$$

These furnish the requisite additional data, and the solution is complete. If we eliminate H between the two equations which contain it, we have

$$k^2\omega'+av'=k^2\omega+av,$$

whence by the relation between $v'$ and $\omega'$ we have

$$(k^2+a^2)\omega'=k^2\omega+av.$$

These equal quantities, each multiplied by M, represent respectively the moment of momentum about the point before and after its fixture.

§ 252. Thus, as a little consideration will show, we might have solved the problem at once, so far as the impulsive change of *motion* is concerned, by noticing that as the impulse is applied at the origin, the moment of momentum about that point will not be altered by it. In fact many problems, which present serious complexity when treated by the direct methods, are solved with comparative ease by such general considerations as the conservation of moment of momentum, or the conservation of energy. The first principle holds good when there is no resultant couple, or impulsive couple, round the origin; the second when no work on the whole is done by or against the forces or impulses.

Combined rolling and sliding.

§ 253. We have given instances of pure sliding, and of pure rolling, in one plane, and will now give a single instance of combined rolling and sliding. A common but instructive case of the problem we propose to consider is that of a hoop thrown forwards and at the same time made to rotate, so that after a time it stops, and finally rolls backwards to the hand. Other cases are furnished by a "following stroke" or a "screw-back" with a billiard ball.

Let the axis of $x$ be parallel to the motion of translation of a sphere or cylinder moving on a horizontal plane. Then we have, if F be the friction, $a$ the radius of the hoop or ball, the rate of change of momentum = F, and that of moment of momentum about the centre = F$a$.

So long as sliding continues, F is constant, and equal to the product $\mu Mg$ of the normal pressure and the coefficient of kinetic friction. Hence at time $t$, if $u_0$ and $\omega_0$ be the initial velocities of translation and of rotation,

$$u=u_0-\mu gt,$$
$$k^2\omega=k^2\omega_0-\mu gat.$$

These equations cease to be true when the sliding ceases, *i.e.*, when we have pure rolling, of which the geometrical condition is

$$u+a\omega=0.$$

This gives $$u_0+a\omega_0-\mu g(a^2/k^2+1)t_0=0,$$

or $$t_0=\frac{k^2(u_0+a\omega_0)}{\mu g(a^2+k^2)}.$$

At time $t_0$ and ever after we have

$$u=u_0-\frac{k^2(u_0+a\omega_0)}{k^2+a^2}=a\frac{au_0-k^2\omega_0}{k^2+a^2},$$

$$\omega=\omega_0-\frac{au_0+a^2\omega_0}{k^2+a^2}=\frac{k^2\omega_0-au_0}{k^2+a^2}.$$

Hence, if the body be projected in the positive direction, its ultimate motion will be in the negative direction if $au_0-k^2\omega_0$ be negative, *i.e.*, if the initial angular velocity be positive, and greater than $au_0/k^2$; which is $\frac{5}{2}u_0/a$ in the case of a sphere. Thus, at starting, the linear velocity of the point of contact with the plane must bear to that of translation of the ball a ratio of over 7 : 2 if it is to stop and return. In the case of a hoop this ratio must be at least 2 : 1.

Rigid body with point fixed.

§ 254. We pass now to the case of a rigid body one point only of which is fixed. As we have already seen (§ 234) this has only to be compounded with the motion of the whole mass, supposed concentrated at the point, in order to give the most general motion of which a rigid body is capable. The geometrical processes which have been applied to this problem, though in many respects of great power and elegance, cannot be introduced here. We will therefore give the more important results in a brief analytical form, and then geometrically exhibit their application.

Recurring to the general equations

$$\Sigma m(xy-y\ddot{x})=\Sigma(xY-yX)=N,\ \&c.,$$

we may transform the left hand members as follows.

Let $\omega_x$, $\omega_y$, $\omega_z$ be the angular velocities of the body about the fixed axes of $x$, $y$, $z$ respectively. Then (§ 77) we have

$$\dot{x}=z\omega_y-y\omega_z,\ \&c.$$

From these we have three equations of the type

$$\ddot{x}=z\dot{\omega}_y-y\dot{\omega}_z+\dot{z}\omega_y-\dot{y}\omega_z$$
$$=z\dot{\omega}_y-y\dot{\omega}_z+(y\omega_z-x\omega_y)\omega_y-(x\omega_z-z\omega_x)\omega_z.$$

Thus we have

$$\Sigma\dot{y} - y\dot{z} = (x^2+y^2)\dot{\omega}_z - yz\dot{\omega}_y - zx\dot{\omega}_x + xz\omega_y\omega_z - xy\omega_z\omega_x + (x^2-y^2)\omega_x\omega_y - xy(\omega_x^2-\omega_y^2).$$

Now if the fixed axes be taken so as to coincide at a particular instant with the principal axes of the body passing through the point which is regarded as fixed, the terms involving factors of the form $\Sigma(mxy)$, &c., necessarily vanish (§ 237). Also we have

$$\Sigma m(x^2-y^2) = \Sigma m(x^2+z^2-y^2-z^2),$$

so that, if the principal moments of inertia of the body be A, B, C respectively, the dynamical equations become

$$C\dot{\omega}_z + (B-A)\omega_x\omega_y = N, \text{ &c.}$$

But it was proved in § 79 that when the angular velocities of a rigid body are referred to moving and to fixed axes, which coincide at a particular instant, not only are the angular velocities but also the angular accelerations equal at that instant in the two systems. Thus, if $\omega_1$, $\omega_2$, $\omega_3$ be the angular velocities of the body about its principal axes, the equations just obtained take the form (due to Euler)

$$A\dot{\omega}_1 + (C-B)\omega_2\omega_3 = L,$$
$$B\dot{\omega}_2 + (A-C)\omega_3\omega_1 = M,$$
$$C\dot{\omega}_3 + (B-A)\omega_1\omega_2 = N.$$

When $\omega_1$, $\omega_2$, $\omega_3$ are found, in any particular case, from these equations, the actual orientation of the body at any time can be calculated from them by the kinematical processes of § 81. The position in space of the point of the body which has been hitherto treated as fixed is to be calculated separately by the processes already explained for kinetics of a particle, and thus the motion of the body is completely determined—in the sense that the difficulties of the further steps are of a purely mathematical nature.

Rigid body under no forces.

When the forces applied to the body have a single resultant, which either vanishes or passes through the origin, the right-hand terms disappear from Euler's equations. Multiply the equations by $\omega_1$, $\omega_2$, $\omega_3$ respectively, and add. We thus obtain

$$A\omega_1\dot{\omega}_1 + B\omega_2\dot{\omega}_2 + C\omega_3\dot{\omega}_3 = 0,$$

whence
$$A\omega_1^2 + B\omega_2^2 + C\omega_3^2 = 2T \quad . \quad . \quad . \quad . \quad . \quad (1),$$

—the statement that the kinetic energy is constant. Again, multiply by $A\omega_1$, $B\omega_2$, $C\omega_3$ respectively, and add. Then we have

$$A^2\omega_1\dot{\omega}_1 + B^2\omega_2\dot{\omega}_2 + C^2\omega_3\dot{\omega}_3 = 0,$$

whence
$$A^2\omega_1^2 + B^2\omega_2^2 + C^2\omega_3^2 = D^2 \quad . \quad . \quad . \quad . \quad . \quad . \quad (2),$$

expressing the constancy of *amount* of moment of momentum.

But if, in these equations, we now choose to regard $\omega_1$, $\omega_2$, $\omega_3$ as the coordinates, parallel to the principal axes, of the extremity of a line which represents, in magnitude and direction, the instantaneous axis, we see that that axis is a central vector of each of the ellipsoids (1) and (2). Hence the instantaneous axis describes, relatively to the body, a cone of the second order. Since T and D are the only arbitrary coefficients in the equations, all the ellipsoids (1) or (2) are similar and similarly situated. The curve of intersection of (1) and (2) projected on the plane of the axes A and B has the equation

$$A(C-A)\omega_1^2 + B(C-B)\omega_2^2 = 2TC - D^2.$$

This represents an ellipse if the terms on the left have the same sign, *i.e.*, if C is either greater or less than each of A and B. Hence, if the body be originally rotating about an axis nearly coinciding either with the axis of greatest or that of least moment of inertia, it will continue to do so. These two cases are exemplified respectively by a quoit and by an elongated rifle bullet,—at least in so far as the resistance of the air does not interfere with their motion. But if the body be originally rotating about an axis nearly coinciding with the axis of intermediate moment of inertia, the curve indicated by the equation above is an hyperbola or a pair of straight lines through the origin; and the instantaneous axis travels, in general, far away from its first position in the body. We will henceforth look on A, B, C as in descending order of magnitude. It is obvious from the mode in which they are formed that $A = B + C$ only when the body is a plate. Hence, generally, any two of A, B, C are together greater than the third. Also by multiplying (1) by A, and comparing it term by term with (2), we see that $2AT > D^2$; similarly $2CT < D^2$.

To complete the examination of the immediate results of Euler's equations in this case, let us find how the length of the instantaneous axis, considered as a common vector-radius of the ellipsoids (1) and (2), depends on the time.

Let
$$\Omega^2 = \omega_1^2 + \omega_2^2 + \omega_3^2 \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (3);$$

$$\Omega\dot{\Omega} = \omega_1\dot{\omega}_1 + \omega_2\dot{\omega}_2 + \omega_3\dot{\omega}_3$$
$$= -\left(\frac{C-B}{A} + \frac{A-C}{B} + \frac{B-A}{C}\right)\omega_1\omega_2\omega_3 = -\frac{\Delta}{ABC}\omega_1\omega_2\omega_3,$$

where $\Delta$ is the determinant

$$\begin{vmatrix} 1 & 1 & 1 \\ A & B & C \\ A^2 & B^2 & C^2 \end{vmatrix} = -(C-B)(B-A)(A-C).$$

Now (1), (2), (3) are linear equations in $\omega_1^2$, $\omega_2^2$, $\omega_3^2$, and from them we have three equations like

$$\Delta\omega_1^2 = BC(C-B)\Omega^2 + 2T(B^2-C^2) + D^2(C-B)$$
$$= BC(C-B)\{\Omega^2 - a\},$$

where
$$a = \frac{2T(B+C) - D^2}{BC}$$

is, by the remark above, essentially positive. Hence

$$\Delta^3\omega_1^2\omega_2^2\omega_3^2 = A^2B^2C^2(C-B)(B-A)(A-C)(\Omega^2-a)(\Omega^2-b)(\Omega^2-c)$$
$$= A^2B^2C^2\Delta(a-\Omega^2)(b-\Omega^2)(c-\Omega^2).$$

Thus
$$\Omega\dot{\Omega} = \sqrt{(a-\Omega^2)(b-\Omega^2)(c-\Omega^2)};$$

whence $\Omega^2$ is at once found by elliptic functions. $\Omega$ known, we have $\omega_1$, $\omega_2$, $\omega_3$, and then by the method of § 81 we have the complete analytical determination of the position of the body in terms of the time.

Poinsot's rolling ellipsoid.

§ 255. Such a solution, however, fails to give so clear a conception of the nature of the motion as is afforded by the very elegant geometrical representation discovered by Poinsot. We may arrive at it by considering the tangent plane to (1) at the extremity of the radius $\Omega$. If $x$, $y$, $z$ be the current coordinates of that plane, its equation is

$$A\omega_1(\omega_1 - x) + B\omega_2(\omega_2 - y) + C\omega_3(\omega_3 - z) = 0,$$

so that the perpendicular from the origin upon it is equal, by (2), to $2T/D$, a constant. The direction cosines of this perpendicular are proportional to $A\omega_1$, $B\omega_2$, $C\omega_3$, the component moments of momentum. Hence it is the axis of resultant moment of momentum, and is therefore (§ 166) fixed in direction in space. The tangent plane to (1) at the extremity of the instantaneous axis is therefore a fixed plane, and the ellipsoid (1) rolls upon it as if it were perfectly rough. From this we can of course find the equation of the curve of contact with the plane, and thence that of the cone, fixed in space, on which the cone of instantaneous axes in the body rolls, as in § 75. The latter cone is of course given by the intersection of (1) and (2).

Sylvester's addition to Poinsot's construction.

To complete this beautiful representation of the motion, all that is necessary is a method of measuring time, something to show the rate of rolling of the ellipsoid on the fixed plane. Many constructions have been given for this purpose, such as Poinsot's "rolling and sliding cone," &c., but none can compare in elegance with that invented by Sylvester. We can only sketch a particular case—sufficient, however, to completely solve the question.

Writing $l$, $m$, $n$ for the direction cosines of the fixed line referred to the principal axes, we have

$$l = A\omega_1/D, \quad m = B\omega_2/D, \quad n = C\omega_3/D \quad . \quad . \quad . \quad . \quad (4).$$

Our equations (1) and (2) may now be written

$$l^2/A + m^2/B + n^2/C = 2T/D^2 \quad . \quad . \quad . \quad . \quad . \quad (1),$$
$$l^2 + m^2 + n^2 = 1 \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (2).$$

Introducing a factor $p$, of dimensions the same as $1/A$, we have from these a third equation

$$l^2(1/A+p) + m^2(1/B+p) + n^2(1/C+p) = 2T/D^2 + p \quad . \quad (5).$$

Now consider an ellipsoid

$$\frac{x^2}{1/A+p} + \frac{y^2}{1/B+p} + \frac{z^2}{1/C+p} = E \quad . \quad . \quad . \quad . \quad (6),$$

which is similar, and similarly situated, to one of the ellipsoids confocal with (1) of § 254. Draw to it a tangent plane perpendicular to the line OL, whose direction cosines are (4). We obtain for the determination of the point of contact Q three equations of the form

$$l = \frac{x}{S(1/A+p)}, \quad m = \frac{y}{S(1/B+p)}, \quad n = \frac{z}{S(1/C+p)}$$

where
$$S^2 = \frac{x^2}{(1/A+p)^2} + \frac{y^2}{(1/B+p)^2} + \frac{z^2}{(1/C+p)^2}.$$

Here $x$, $y$, $z$ are the coordinates of Q, and the distance of the tangent plane from the origin is E/S.

Now (6) gives at once by means of (7)

$$S^2[l^2(1/A+p) + m^2(1/B+p) + n^2(1/C+p)] = E;$$

whence, by (5), $$S^2=\frac{E}{2T/D^2+p}.$$

This is constant, and therefore the new tangent plane is fixed in space.

Let us now find the angular velocity about the fixed line OL of this plane's point of contact Q with the ellipsoid (6).

The direction cosines of the instantaneous axis OP are as $\omega_1, \omega_2, \omega_3$. Those of OQ are as $x, y, z$.

And we have obviously by (4) and (7)

$$\begin{vmatrix} \omega_1 & \omega_2 & \omega_3 \\ x & y & z \\ A\omega_1 & B\omega_2 & C\omega_3 \end{vmatrix}=0.$$

Hence the line OQ lies in the plane containing the instantaneous axis OP and the fixed line OL. The motion of ellipsoid (6) is therefore one of combined sliding and rolling along the new tangent plane. To find the sliding, we must find the angular velocity of Q about the line OL. It is to that about OP, which is $\Omega$, in the ratio of the sines of the angles POQ and QOL.

But $$\sin^2 POQ=1-\frac{(x\omega_1+y\omega_2+z\omega_3)^2}{(x^2+y^2+z^2)\Omega^2},$$

and $$\sin^2 QOL=1-\frac{(A\omega_1 x+B\omega_2 y+C\omega_3 z)^2}{(x^2+y^2+z^2)D^2}.$$

By means of the equations (1) and (7) above we find easily

$$\frac{\sin^2 POQ}{\sin^2 QOL}=\frac{D^2p^2}{\Omega^2}.$$

Hence the angular velocity of Q about OL is $Dp$, a constant. Now suppose the plane on which the ellipsoid (6) rolls and slides to become perfectly rough, and to be capable of rotating round OL as an axis, there will no longer be sliding of Q, but the plane will be made to rotate with the constant angular velocity $Dp$. Thus the time of any portion of the motion of the body will be measured out by the angle of forced rotation of this plane.

Quoit. § 256. As a simple example, let us take the case of a quoit, in which A, the moment of inertia about the axis of figure, is greater than either of the equal quantities B and C, which may be referred to any two perpendicular lines in the plane of the quoit. The equations become

$$A\dot{\omega}_1=0, \text{ so that } \omega_1 \text{ is constant},$$
$$B\dot{\omega}_2+(A-B)\omega_3\omega_1=0,$$
$$B\dot{\omega}_3+(B-A)\omega_1\omega_2=0.$$

Put for a moment $\frac{A-B}{B}\omega_1=n$, then we have

$$\dot{\omega}_2+n\omega_3=0, \quad \dot{\omega}_3-n\omega_2=0.$$

These give by eliminating $\omega_3$

$$\ddot{\omega}_2+n^2\omega_2=0.$$

Hence $$\omega_2=P\cos(nt+Q),$$
$$\omega_3=-n^{-1}\dot{\omega}_2=P\sin(nt+Q).$$

The resultant of these is an angular velocity P, about an axis in the plane of the axes of B and C, and making an angle $nt+Q$ with the axis of B. Hence the instantaneous axis describes in the body a right cone whose axis is that of figure; it moves round it in the *same* direction as that in which the body is rotating, and with angular velocity $n$. The fixed cone in space is also, obviously, a right cone and the other rolls on it *externally*.

Cylinder. If instead of a quoit the body be a long stick or cylinder, we have A = B > C, and the equations become

$$A\dot{\omega}_1+(C-A)\omega_2\omega_3=0,$$
$$A\dot{\omega}_2+(A-C)\omega_3\omega_1=0,$$
$$C\dot{\omega}_3=0.$$

The last gives $\omega_3=$ constant, and, if

$$n=\frac{A-C}{A}\omega_3,$$

the first two equations are

$$\dot{\omega}_1-n\omega_2=0, \quad \dot{\omega}_2+n\omega_1=0.$$

Thus $$\ddot{\omega}_1+n^2\omega_1=0, \quad \omega_1=P\cos(nt+Q),$$

and $$\omega_2=-P\sin(nt+Q).$$

This indicates a rotation of the axis of constant angular velocity P in the *negative* direction. Everything else is as before, but the cone fixed in the body rolls on the *inside* of that fixed in space.

Gyroscopic pendulum. § 257. Next let us take the case of a pendulum bob, supported by a flexible but untwistable wire, and containing a gyroscope whose axis is in the direction of the length of the pendulum. Here we may use, for variety, Lagrange's equations. For simplicity we suppose the centres of inertia of the bob and gyroscope to lie in the axis, and the bob to be symmetrical about the direction of the length of the pendulum.

Let the moment of inertia of the whole about the axis of symmetry be A when the gyroscope is supposed to be prevented from turning relatively to the bob, and let the other two principal moments about the point of suspension be B. Let that of the gyroscope about its axis be C. Then, if $\theta$ be the inclination to the vertical, $\phi$ the azimuth of the pendulum, and $\psi$ a quantity denoting the position of the gyroscope with reference to a definite plane in the bob passing through its axis, we easily find

$$2T=A(1-\cos\theta)^2\dot{\phi}^2+B(\dot{\theta}^2+\sin^2\theta\dot{\phi}^2)+C[\dot{\psi}-(1-\cos\theta)\dot{\phi}]^2,$$
$$V=Mgl(1-\cos\theta)=V_0(1-\cos\theta), \text{ suppose},$$

where M is the whole mass, and $l$ the distance from the point of suspension to the centre of inertia of the whole.

The general treatment of this complex problem cannot be attempted here. We may, however, easily obtain useful and characteristic results in some special simple cases, which will enable us to form a general idea of the nature of the motion.

Thus, suppose if possible $\theta$ to be constant. This is the *Conical Gyroscopic Pendulum*. We easily find the equations

Conical gyroscopic pendulum.

$$\dot{\psi}-(1-\cos\theta)\dot{\phi}=\Omega=\text{const.}$$
$$(A(1-\cos\theta)+B\cos\theta)\dot{\phi}^2-C\Omega\dot{\phi}=V_0.$$

For any assigned values of $\Omega$ and $\theta$, this shows what will be the corresponding value of $\dot{\phi}$. But it also shows that if we change simultaneously the signs only of $\Omega$ and $\dot{\phi}$, the value of $\theta$ is unaltered. Thus, reversal of the direction of rotation of the gyroscope involves reversal of the direction of motion of the bob, if the time of rotation is to be unaltered. But to any assigned values of $\theta$ and $\Omega$ two values of $\dot{\phi}$ correspond. As $\theta$ cannot, in the case considered, exceed $\frac{1}{2}\pi$, the multiplier of $\dot{\phi}^2$ is essentially positive. So is $V_0=Mgl$. Hence the values of $\dot{\phi}$ are real; and one is positive, the other negative. Thus the pendulum, with any rate of rotation of the gyroscope, may be made to move in any horizontal circle; but the angular velocity will be greater when it is in the same sense as that of the rotation of the gyroscope than when it is in the opposite sense. When $\theta$ is so small that $\theta^2$ may be neglected, we have

$$B\dot{\phi}^2-C\Omega\dot{\phi}=V_0,$$
or $$2B\dot{\phi}=C\Omega\pm\sqrt{4BV_0+C^2\Omega^2}.$$

To give a numerical example, let the mass of the gyroscope be $\frac{n-1}{n}M$; let $B=Ml^2$, $C=\frac{n-1}{n}M\frac{l^2}{c^2}$, then

$$2\dot{\phi}=\frac{(n-1)\Omega}{nc^2}\pm\sqrt{4\frac{g}{l}+\left(\frac{n-1}{nc^2}\right)^2\Omega^2}.$$

If $n=5$, $c=10$, $g=10l$ (which are fair approximations to the dimensions of the ordinary form of the instrument),

$$\dot{\phi}=\frac{2\Omega}{500}\pm\sqrt{10+\frac{4}{(500)^2}\Omega^2}.$$

Suppose the gyroscope to revolve 100 times per second, then $\Omega=200\pi$ practically, and

$$\dot{\phi}=\tfrac{2}{5}\pi\pm\sqrt{10+\tfrac{1}{25}\pi^2}=2\cdot513\pm4\cdot039$$
$$=6\cdot552 \text{ or } -1\cdot526.$$

The angular velocity, when the gyroscope is not rotating, would be that of the corresponding conical pendulum,

$$\sqrt{g/l}=\pm3\cdot162;$$

so that in this case the gyroscopic pendulum would rotate about twice as fast, or only about half as fast, as the ordinary conical pendulum, according as it rotated with or against the gyroscope.

If we had taken $\Omega=10\pi$ we should have found

$$\dot{\phi}=3\cdot29 \text{ or } -3\cdot04, \text{ nearly}.$$

Thus the slower the gyroscope rotates the slower is the conical pendulum motion in the same direction, and the quicker that in the opposite direction.

## Statics of a Chain or Perfectly Flexible Cord.

§ 258. Axiom.—*When a body or system is in equilibrium under the action of any forces, additional constraints will not disturb the equilibrium.* Compare § 193.

This principle is of very great use in forming the fundamental equations of fluid equilibrium, and thence those of motion. And we find it of advantage, as will be presently seen, in reducing to elementary geometry the problem of the equilibrium of a chain, or perfectly flexible cord.

We may treat this problem, called that of a "catenary," by any one of the following methods:—(1) by investigating, as a question of statics of a particle, the conditions of equilibrium of a single link; (2) by imagining a finite portion of the chain to become rigid in its Catenary.

equilibrium form,—assuming by the axiom above, that it will remain in equilibrium, and then treating the question by the methods employed for a rigid body; (3) by employing the energy test of equilibrium as in § 198.

§ 259. We exemplify each of these methods in the specially important case of the ordinary catenary.

Common catenary.

*A uniform chain hangs between two fixed points, find the tension at any point and the curve in which the chain hangs.*

*First Method.*—Let $\mu$ be the mass of unit length of the chain; T the tension at the point $x, y, z$; $s$ the length of the chain to $x, y, z$ from some assigned point; and let the axis of $y$ be taken vertically. Then we have for the equilibrium of the element $\delta s$, considered as a material particle,

$$T\frac{dx}{ds}-\left(T\frac{dx}{ds}+\frac{d}{ds}\left(T\frac{dx}{ds}\right)\delta s\right)=0,$$

$$T\frac{dy}{ds}+\mu g-\left(T\frac{dy}{ds}+\frac{d}{ds}\left(T\frac{dy}{ds}\right)\delta s\right)=0,$$

$$T\frac{dz}{ds}-\left(T\frac{dz}{ds}+\frac{d}{ds}\left(T\frac{dz}{ds}\right)\delta s\right)=0.$$

Omitting the terms which cancel one another, and dividing by $\delta s$, these become

$$\frac{d}{ds}\left(T\frac{dx}{ds}\right)=0,\quad \frac{d}{ds}\left(T\frac{dy}{ds}\right)=\mu g,\quad \frac{d}{ds}\left(T\frac{dz}{ds}\right)=0.$$

From the first and third it follows that $dz/dx$ is constant, *i.e.*, the chain hangs in a vertical plane. We may take it as that of $xy$, and the equations are reduced to the first two.

The first gives

$$T\frac{dx}{ds}=T_0,$$

showing that the horizontal component of the tension is constant throughout the whole length of the chain. Substituting for T in the second, it becomes

$$\frac{d}{ds}\left(\frac{dy}{dx}\right)=\frac{\mu g}{T_0}.$$

The quantity on the right is evidently of $[L^{-1}]$ dimensions, because that on the left is so; and thus we may write

$$\frac{\mu g}{T_0}=\frac{1}{a},\quad \text{or}\quad T_0=\mu g a.$$

Hence $a$ is the length of a portion of the chain whose weight is equal to the constant horizontal component of the tension.

The equation now becomes

$$\frac{d^2y}{dx^2}=\frac{1}{a}\frac{ds}{dx}=\frac{1}{a}\sqrt{1+\left(\frac{dy}{dx}\right)^2}.$$

Integrating, we have

$$\frac{dy}{dx}+\sqrt{1+\left(\frac{dy}{dx}\right)^2}=C\varepsilon^{\frac{x}{a}}.$$

If we now assume that the axis of $y$ passes through the point at which the chain is horizontal, we have at that point $x=0, \frac{dy}{dx}=0$, and therefore $C=1$. Thus

$$\sqrt{1+\left(\frac{dy}{dx}\right)^2}+\frac{dy}{dx}=\varepsilon^{\frac{x}{a}}.$$

Taking the reciprocal of each side, we have

$$\sqrt{1+\left(\frac{dy}{dx}\right)^2}-\frac{dy}{dx}=\varepsilon^{-\frac{x}{a}}.$$

Subtracting,

$$2\frac{dy}{dx}=\varepsilon^{\frac{x}{a}}-\varepsilon^{-\frac{x}{a}},$$

or

$$2\frac{y}{a}=\varepsilon^{\frac{x}{a}}+\varepsilon^{-\frac{x}{a}};$$

no constant being added if we assume the axis of $x$ so that $y=a$, $x=0$ together. This is the equation of the curve required.

If we take the sum, instead of the difference, of the above equations, we find

$$2\frac{ds}{dx}=\varepsilon^{\frac{x}{a}}+\varepsilon^{-\frac{x}{a}};$$

so that

$$\frac{2s}{a}=\varepsilon^{\frac{x}{a}}-\varepsilon^{-\frac{x}{a}},$$

$s$ being measured from the axis of $y$.

But the tension at $x, y$ is, as above,

$$T=T_0\frac{ds}{dx}=T_0\frac{y}{a}=\mu g y.$$

Hence the tension at any point of the chain is equal to the weight of a length of the chain equal to the ordinate at that point.

Chain over parallel rails.

Thus if a chain of finite length be laid over two smooth parallel rails, its ends, when the whole is equilibrium, will be in the horizontal line corresponding to the axis of $x$ in the above investigation, the middle part of the chain forming part of the catenary. When a given length $2l$ of chain rests in equilibrium on two smooth parallel rails at the same level, we have therefore $s+y=l$, while $x=b$, the half distance between the rails.

By the above expressions for $y$ and $s$ in terms of $x$, this leads to the equation

$$a\varepsilon^{\frac{b}{a}}=l,$$

which determines $a$ when $b$ and $l$ are given. From this equation, as the minimum value of the left-hand side occurs when $a=b$, we see that the least length of chain for which equilibrium is possible under the conditions is equal to $\varepsilon$ times the distance between the rails.

§ 260. *Second Method.*—The chain being in equilibrium, suppose any finite arc of it, as PQ (fig. 64), to become rigid. The forces acting on PQ are three—the tensions $T_1$ and $T_2$ at its ends, and its weight W acting at its centre of inertia. But three forces in equilibrium are in one plane (§ 221). Hence the curve is in one vertical plane. Also, as the two tensions are not parallel to one another, the lines of action of all three forces meet in one point. Hence there is no couple, and the conditions are simply

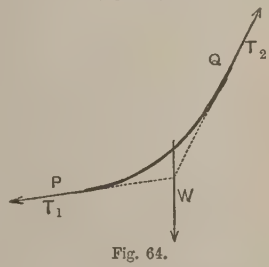

Fig. 64.

$$T_2\cos\theta_2-T_1\cos\theta_1=0,$$
$$T_2\sin\theta_2-T_1\sin\theta_1-W=0;$$

where $\theta_1$, $\theta_2$ are the inclinations to the horizon of the tangents at the ends of the portion solidified. The first asserts that the horizontal part of the tension is the same at P and Q, *i.e.*, all through the chain. The second asserts that the difference of the vertical parts of the tensions at any two points is equal to the weight of the part of the chain between them. By proper mathematical methods these data lead to the results already obtained. In fact the equations we have just obtained are the first integrals of the equations in § 259.

§ 261. *Third Method.*—The potential energy of the chain is

$$\mu g\int y\frac{ds}{dx}dx,$$

with the sole condition

$$\int\frac{ds}{dx}dx=\text{constant},$$

the limits of integration being fixed, and the same for each expression. Hence, by the rules of the calculus of variations, we have the same equations as before.

Mass of chain to hang in given curve.

§ 262. Still supposing gravity to be the only applied force, there are many forms of important questions which can be solved by either of these methods. We will take some simple, but varied, examples.

*Find how the mass of unit length of a chain must vary from point to point so that the catenary may be an assigned plane curve.*

We have, as before,

$$\frac{d}{ds}\left(T\frac{dx}{ds}\right)=0;$$

but our second equation is now

$$\frac{d}{ds}\left(T\frac{dy}{ds}\right)=\mu g,$$

where $\mu$ is an unknown function of $s$. The third equation, being of the same form as the first, shows that the curve is in a vertical plane, and is thenceforth unnecessary.

As before, we have

$$T\frac{dx}{ds} = T_0,$$

and

$$\frac{d}{ds}\left(\frac{dy}{dx}\right) = \frac{\mu g}{T_0}.$$

Now, from the assigned equation of the catenary, the left-hand member can be expressed as a function of $s$, and thus we have the solution of the problem. For example, suppose the chain is to hang in an arc of an assigned circle. Referred to the lowest point of the circle, the equation is

$$x^2 = 2ay - y^2,$$

where $a$ is the radius. From this we have

$$\frac{dy}{dx} = \frac{x}{a-y} = \tan\frac{s}{a},$$

so that

$$\mu = \frac{T_0}{ag}\sec^2\frac{s}{a}.$$

The tension at the lowest point is thus equal to the weight of a piece of chain like that at the vertex, and of length equal to the radius of the circle; the mass per unit length becomes infinite at the end of a horizontal diameter.

Suspension bridge.

Next *find the form of the chain when the mass of any arc is proportional to its horizontal projection.* This is a rough approximation to the case of a suspension bridge where the roadway is uniform, and much more massive than the chains, to which it is attached throughout by vertical ties. The equations are as before, but the additional condition takes the form

$$\mu\frac{ds}{dx} = \mu_0, \text{ a constant.}$$

This gives

$$\frac{d^2y}{dx^2} = \frac{\mu_0 g}{T_0},$$

and the chain forms a parabola whose vertex is downwards, and whose axis is vertical.

Catenary of uniform strength.

As a final example, we have what is called the *catenary of uniform strength*; that is, *the form in which a chain hangs when the tension at every point is proportional to the breaking stress at that point.* Here we suppose the strength to be proportional to the section, *i.e.*, to the mass per unit length. This gives the condition

$$T = e\mu.$$

Hence

$$\frac{d}{ds}\left(\frac{dy}{dx}\right) = \frac{g}{eT_0}T = \frac{g}{e}\frac{ds}{dx},$$

or

$$\frac{d^2y}{dx^2} = \frac{1}{a}\left(\frac{ds}{dx}\right)^2 = \frac{1}{a}\left(1 + \left(\frac{dy}{dx}\right)^2\right)$$

where $a = c/g$.

This gives

$$\frac{dy}{dx} = \tan\left(\frac{x}{a} + C\right);$$

and the complete integral may be written, by proper selection of origin, in the final form

$$\varepsilon^{\frac{y}{a}} = \sec\frac{x}{a}.$$

Limit of span.

This curve has obviously two vertical asymptotes distant $\pm\frac{1}{2}\pi a$ from the axis of $y$. The quantity $a$ is directly as the tenacity of the material; and thus we see that there is a limit (even in this simplest case) to the span of a chain, however strong, formed of any known kind of matter.

It is a very curious fact that, if we write the equation of this catenary in terms of the arc and the radius of curvature, it becomes identical with that of the common catenary in terms of Cartesian coordinates, horizontal and vertical. For we see at once that

$$\frac{ds}{dx} = \sec\frac{x}{a},$$

so that

$$\varepsilon^{\frac{s}{a}} = \sqrt{\left(1+\sin\frac{x}{a}\right)\left(1-\sin\frac{x}{a}\right)};$$

while by the previous equations

$$\frac{1}{\rho} = \frac{\frac{d^2y}{dx^2}}{\left(\frac{ds}{dx}\right)^3} = \frac{1}{a}\frac{1}{\frac{ds}{dx}} = \frac{\cos\frac{x}{a}}{a}$$

Thus finally,

$$\frac{2\rho}{a} = \varepsilon^{\frac{s}{a}} + \varepsilon^{-\frac{s}{a}}.$$ Compare § 259.

§ 263. When the chain is not uniform, and when it is subject to the action of other forces than, or besides, gravity, the equations are general. Catenary general.

$$\frac{d}{ds}\left(T\frac{dx}{ds}\right) = -\mu X, \quad \frac{d}{ds}\left(T\frac{dy}{ds}\right) = -\mu Y, \quad \frac{d}{ds}\left(T\frac{dz}{ds}\right) = -\mu Z,$$

where X, Y, Z are the component forces on unit mass. These three equations involve the unknown quantities T, $x$, $y$, $z$, and $s$ only; for $\mu$ is supposed to be given in terms of $s$. Two relations only among $x$, $y$, and $z$ are wanted (for $s$ is known in terms of $x$, $y$, $z$); so that the equations are necessary and sufficient to give these relations and the remaining unknown T.

The first members of these equations consist each of two terms:—

$$\frac{dT}{ds} \text{ multiplied respectively by } \frac{dx}{ds}, \frac{dy}{ds}, \frac{dz}{ds},$$

and

$$\frac{T}{\rho} \text{ multiplied by } \rho\frac{d^2x}{ds^2}, \quad \rho\frac{d^2y}{ds^2}, \quad \rho\frac{d^2z}{ds^2};$$

$\rho$ being the radius of curvature of the chain. Hence (§ 22) we conclude that, so far as the tension alone is concerned, the forces on an elementary unit of length of the chain are $dT/ds$ in the direction of the tangent, and $T/\rho$ in the direction of the radius of absolute curvature. These must balance the corresponding components of the external forces on the element. Hence we see that the resultant of the applied forces lies, at every point, in the osculating plane. Thus we have

$$\frac{dT}{ds} = -\mu\left(X\frac{dx}{ds} + Y\frac{dy}{ds} + Z\frac{dz}{ds}\right) = -S,$$

$$\frac{T}{\rho} = -\mu\left(X\rho\frac{d^2x}{ds^2} + Y\rho\frac{d^2y}{ds} + Z\rho\frac{d^2z}{ds^2}\right) = -N.$$

Here S and N are the tangential and normal components of the applied forces per unit length of the chain.

But when a unit particle moves in a curve, we have always Catenary as path of particle.

$$\frac{dv}{dt} = v\frac{dv}{ds} = S', \text{ and } \frac{v^2}{\rho} = N',$$

where S' and N' are the normal and tangential components of the requisite force. If we write these in the form

$$\frac{dv}{ds} = \frac{S'}{v}, \quad \frac{v}{\rho} = \frac{N'}{v},$$

and suppose that the curve in which the particle moves is the same as the catenary above, while the speed at each point has the same numerical value as the tension, we see that we must have

$$\frac{S'}{v} = \frac{S'}{T} = -S, \quad \frac{N'}{v} = \frac{N'}{T} = -N;$$

or

$$S' = -ST, \qquad N' = -NT.$$

Thus the catenary will be the free path of the particle provided the force applied at any point is equal to the reverse of the product of that acting on the chain by the numerical value of the tension of the chain at that point.

Conversely, if we take any case of free motion of a particle, a uniform chain will hang in the corresponding orbit under the action of the same forces each reversed, and divided by the numerical value of the speed at the corresponding point of the orbit. Thus we can at once pass from particle kinetics to corresponding cases of catenaries.

In the case of a projectile, the path is a parabola, the force is constant and parallel to the axis, and the speed is as the square-root of the distance from the directrix. Hence, that the parabola may be a catenary under gravity, it must be turned vertex downwards; and the mass of the chain per unit length at any point must be inversely as the square root of the distance from the directrix. It is easily found from this that the mass of any arc of the chain must be proportional to the length of its horizontal projection, as in the second problem solved in § 262. Parabolic catenary.

In the case of a planet we have Elliptic catenary.

$$v^2 = \mu(2/r - 1/a).$$

Hence a chain will hang in an ellipse if it be *repelled* from one focus by a force varying inversely as the square of the distance, the mass per unit length of the chain being directly as the square root of the distance from that focus and inversely as the square root of the distance from the other. If the chain be uniform, the law of the repulsive force from the first focus must be $1/\sqrt{r^3r'}$ instead of $1/r^2$, where $r$, $r'$ are the distances from the two foci.

§ 264. When a chain or string is stretched over a curved surface, the surface must exert a reaction on it to keep it in its curved form. The preceding investigation has shown that the force normal to a chain per unit length at any point is balanced by T/$\rho$ per unit of length, which must therefore be the magnitude of the reaction. We

may establish this, however, in a very simple manner, as follows :—

Let AB (fig. 65) be a small portion of the cord, and AC, CB the tangents at its extremities; and let the (small) exterior angle at C be $\theta$. Then, $p$ being the pressure per unit length of the string, we have at once

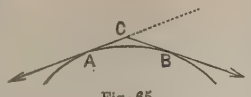

Fig. 65.

$$p.\mathrm{AB} = 2\mathrm{T}\sin\tfrac{1}{2}\theta = \mathrm{T}\theta$$

ultimately. But $\mathrm{AB} = \rho\theta$, so that

$$p = \mathrm{T}/\rho .$$

Rope coiled on rough cylinder.

If there be friction, and if the element of the rope be just about to slip, in consequence of the difference of the tensions at its ends, we have

$$\mathrm{T}' - \mathrm{T} = \mu p.\mathrm{AB} = \mu\mathrm{T}\theta ,$$

so that

$$\mathrm{T}' = \mathrm{T}(1 + \mu\theta) .$$

This leads to the formula for the growth of a sum at compound interest at $\mu$ per cent. payable every instant. Hence for a *finite* angle $\alpha$ we have

$$\mathrm{T}_\alpha = \varepsilon^{\mu\alpha}\mathrm{T}_0 .$$

It is to be remarked here that neither the dimensions nor the form of the curve on which the cord is stretched, provided only it be plane, have any influence on this result, which involves only the coefficient of friction and the angle between the two free portions of the cord.

### Kinetics of a Chain or Perfectly Flexible Cord.

§ 265. The equations of motion of a chain, under the action of any finite forces, are at once formed from those of equilibrium by introducing the forces of resistance to acceleration according to Newton's principle. Here we enter on a subject of extreme importance, but also (at least in the majority of cases) of great mathematical difficulty. One valuable result, however, can be obtained by very simple means.

Wave-velocity on stretched cord.

*A uniformly heavy and perfectly flexible cord, placed in the interior of a smooth tube in the form of any curve, and subject to no external forces, will exert no pressure on the tube if it have everywhere the same tension, and move with a certain definite speed.*

For, as in § 264, the statical pressure due to the curvature of the rope is $\mathrm{T}\theta/\sigma$ per unit of length (where $\sigma$ is the length of the arc AB in that figure) directed inwards to the centre of curvature. Now, the element $\sigma$, whose mass is $m\sigma$ (if $m$ be the mass per unit of length), is moving in a curve whose curvature is $\theta/\sigma$, with speed $v$ (suppose). The requisite force is $\dfrac{mv^2\sigma\theta}{\sigma} = mv^2\theta$, and for unit of length $mv^2\theta/\sigma$. Hence if $\mathrm{T} = mv^2$ the theorem is true. If we suppose a portion of the tube to be straight, and the whole to be moving with speed $v$ parallel to this line, and against the motion of the cord, we shall have the straight part of the cord reduced to rest, and an undulation, of any, but unvarying, form and dimensions, running along it with linear speed $\sqrt{\mathrm{T}/m}$.

Suppose the tension of the cord to be equal to the weight of W pounds, and suppose its length $l$ feet and its own mass $w$ pounds. Then $\mathrm{T} = \mathrm{W}g$, $lm = w$, and the speed of the undulation is $\sqrt{\mathrm{W}lg/w}$ feet per second.

Reflected wave.

266. As will be shown later, when such an undulation reaches a fixed point of the cord or chain, it is *reflected*, and runs back along the cord with the same definite speed. But the reflected form differs from the incident form in being turned about in its own plane through two right angles. When the string is fixed at both ends any disturbance runs along it, backwards and forwards, with this speed, and thus (in a piano or harp) administers periodic shocks to the sounding board, causing it to give out a musical note. The interval between these periodic shocks is of course the time taken by the disturbance in running from end to end of the string. Dividing the length $l$ of the string by the speed above reckoned, we find for this interval the value

$$\sqrt{wl/\mathrm{W}g} = l\sqrt{m/\mathrm{W}g} ,$$

the reciprocal of which is the number of impulses per second. It is thus seen to be directly as the square-root of the tension of the string, inversely as the square-root of its mass per unit of length, and also inversely as its length. These are well-known facts in Acoustics. It is to be observed that there is no necessity for limiting the proposition above to a plane curve, though we have treated the question as if it were such. The demonstration applies even to a knot of any form.

Vibration of musical string.

267. We will now consider more particularly the vibrations of a musical string, whose tension is great and its own mass small.

Forming the equations of motion as above hinted, we have three of the type

$$\frac{d}{ds}\left(\mathrm{T}\frac{dx}{ds}\right) = -\mu(\mathrm{X} - \ddot{x}) .$$

In the special case of a tightly stretched inextensible string, performing very small transverse oscillations, we may greatly simplify these by assuming that no external forces act. This practically means that the weight of the string is negligible in comparison with the tension. If the axis of $x$ be taken to coincide with the undisturbed position of the string, we have to the second order of small quantities

$$s = x .$$

With this the equation above written becomes

$$\frac{d\mathrm{T}}{ds} = 0 ,$$

or the tension is the same throughout. The second and third equations now become

$$\mathrm{T}\frac{d^2y}{dx^2} = \mu\ddot{y} , \qquad \mathrm{T}\frac{d^2z}{dx^2} = \mu\ddot{z} .$$

The $y$ and $z$ disturbances are therefore of the same general character, and perfectly independent of one another. We will therefore confine our attention to one of them. From the equations we see that $\mathrm{T}/\mu$ must be of two linear dimensions, and we will therefore write for it $a^2$. As this quantity must also be of two negative dimensions in time, $a$ represents a speed. What speed will be seen immediately.

The equation in $y$ is now

$$a^2\frac{d^2y}{dx^2} = \ddot{y} ;$$

whose integral is known to be

$$y = f(at - x) + \mathrm{F}(at + x) ,$$

where $f$ and F are arbitrary functions. As we have already seen (§ 53), the first part of the value of $y$ expresses a wave running with speed $a$ along the axis of $x$ in the positive direction; the second part a wave in the negative direction with the same speed. Thus we see that any small disturbance whatever, of a stretched string, gives rise to two series of waves propagated in opposite directions with equal speeds. Also, as the equation is linear, the sum of any two or more particular integrals is also an integral.

One end fixed.

If we suppose one extremity of the string to be fixed at the origin, we have the condition $x = 0$, $y = 0$, and therefore

$$0 = f(at) + \mathrm{F}(at) .$$

As this holds for all values of $t$, the function F is simply the negative of $f$, so that

$$y = f(at - x) - f(at + x) .$$

To investigate what becomes of a disturbance which runs along the cord to the fixed end, let us suppose that $f(r)$ (which, by the remark above, may represent any *part* of a disturbance of the string) is a function which vanishes for all values of $r$ which do not lie between the positive limits $p$ and $q$, but which for values of $r$ between these limits takes definite values. Then at time $t = 0$ we have

$$y = -f(x) ,$$

for, by hypothesis, $f(r)$ vanishes for all negative values of $r$. This denotes a disturbance of the string originally extending from $x = p$

to $x=q$, which runs up to the origin. After the lapse of any interval greater than $q/a$ we have

$$y=f(at-x),$$

for $at+x$ has now become greater than $q$. This is a wave of exactly the same form as before, but the sign of the disturbance and the direction of its propagation are both reversed. Every portion of a wave is therefore reflected, with simple *reversal* of the displacement, as soon as it reaches the fixed end. For we may take the limits $p$ and $q$ as close together as we choose.

Both ends fixed.

Now suppose the string to have another fixed point at $x=l$. Then we have

$$0=f(at-l)-f(at+l).$$

Thus $f$ is (§ 67) a periodic function, of period $2l/a$, and can therefore be expressed as a series of simple harmonic terms of the full period, half period, one-third period, &c. Hence we may write, the coefficient $\frac{1}{2}$ being put in for convenience,

$$\begin{aligned}y=&\tfrac{1}{2}\Sigma_1^{\infty}A_m\cos\pi ml^{-1}(at-x)+\tfrac{1}{2}\Sigma_1^{\infty}B_m\sin\pi ml^{-1}(at-x)\\&-\tfrac{1}{2}\Sigma_1^{\infty}A_m\cos\pi ml^{-1}(at+x)-\tfrac{1}{2}\Sigma_1^{\infty}B_m\sin\pi ml^{-1}(at+x)\\=&\Sigma_1^{\infty}A_m\sin\pi ml^{-1}at\sin\pi ml^{-1}x-\Sigma_1^{\infty}B_m\cos\pi ml^{-1}at\sin\pi ml^{-1}x.\end{aligned}$$

This expression contains the complete solution of the problem. To adapt it to any particular case, we must know at some definite time (say $t=0$) the value of $y$ in terms of $x$, *i.e.*, the initial disturbance; also the corresponding value of $\dot{y}$. We have then

$$y_0=-\Sigma_1^{\infty}B_m\sin\pi ml^{-1}x,$$

$$\dot{y}_0=\frac{\pi a}{l}\Sigma_1^{\infty}mA_m\sin\pi ml^{-1}x.$$

As $y_0$, $\dot{y}_0$ are given in terms of $x$, we can find, by the process of § 67, the values of $A_m$ and $B_m$, and thence the required value of $y$.

Oscillations of a chain fixed at one end.

268. As another example, suppose a uniform chain to be suspended by one end, and to make small oscillations in a vertical plane.

We cannot enter here into details; so we simply assume that elementary persistent harmonic solutions are possible, or, what comes to the same thing, that there are *permanent* forms in which the chain can rotate about the vertical from the point of suspension.

If the axis of $x$ be vertical, the equations of motion are

$$\frac{d}{ds}\left(\mathrm{T}\frac{dx}{ds}\right)=-\mu(g-\ddot{x}),\qquad \frac{d}{ds}\left(\mathrm{T}\frac{dy}{ds}\right)=\mu\ddot{y};$$

where $\mu$ is the mass of unit length of the chain. As the oscillations are supposed to be small, we may neglect the change in the vertical ordinate of any point of the chain, because it must be of the second order of small quantities if the horizontal displacement is of the first order. Hence we may put everywhere $x$ for $s$, and therefore consider $x$ to be independent of $t$. Thus the first equation becomes

$$\frac{d\mathrm{T}}{dx}=-\mu g;$$

whence

$$\mathrm{T}=\mu g(l-x),$$

where $l$ is the length of the chain. The second equation then becomes

$$(l-x)\frac{d^2y}{dx^2}-\frac{dy}{dx}=\frac{1}{g}\ddot{y};$$

or, if we measure $x$ from the lower end of the chain upwards,

$$x\frac{d^2y}{dx^2}+\frac{dy}{dx}=\frac{1}{g}\ddot{y}.$$

The complete integral of this equation would be much more general than we require, for it would express every possible small motion of the chain, however apparently irregular. What we seek are the fundamental modes of simple harmonic oscillation, any number of which, as in the case of a musical string, may be superposed. Hence we may write

$$y=\eta\sin(nt+\alpha),$$

where $n$ is a numerical quantity as yet undetermined, but which is confined to one or other of a series of definite values; $\eta$, on the other hand, is a function of $x$ only. With this value of $y$ the equation becomes

$$x\frac{d^2\eta}{dx^2}+\frac{d\eta}{dx}+\frac{n^2}{g}\eta=0.$$

By the usual method of undetermined coefficients we easily find the particular integral

$$\eta_0=\mathrm{A}\left(1-\frac{n^2x}{g}+\frac{n^4x^2}{2^2g^2}-\frac{n^6x^3}{2^23^2g^3}+\&c.\right)\quad .\quad .\quad .\quad (1).$$

This series is obviously convergent for all finite values of $n^2x/g$.

The general integral is of the form

$$\eta=\mathrm{B}(\eta_1+\eta_0\log x)+\mathrm{A}\eta_0;$$

where $\eta_1$ is a function of $x$, finite for all values of $x$, but which we need not determine. For it is clear that, to suit our present purpose, we must put $\mathrm{B}=0$; otherwise we should have $\eta$ infinite at $x=0$. Thus (1) is the expression we require under the limitations above imposed.

The quantity A represents the semi-amplitude of oscillation of the lower extremity of the chain. The condition that the upper end is fixed gives $\eta_0=0$ for $x=l$, *i.e.*,

$$0=1-\frac{n^2l}{g}+\frac{n^4l^2}{2^2g^2}-\frac{n^6l^3}{2^23^2g^3}+\&c.$$

The roots of this equation (which are all real and positive) give the values of $n$ for the several fundamental modes of vibration.

We have $\eta_0=0$ for the following values of $n^2l/g$: 1·454, 7·62, 18·74, 34·79, &c.

From these we find for the periods of the various simple disturbances the following multiples of the period of a simple pendulum equal in length to the chain, viz., 0·83, 0·36, 0·23, 0·17, &c. When $n^2l/g$ has the least of the above values, the chain is always entirely on one side of the vertical, and the time of a complete oscillation is to that of a simple pendulum of the same length as 5 : 6 nearly.

269. When a free chain, at rest, has an impulsive tension applied at one end, the calculation of the consequent impulsive tension at the different parts of the chain and the velocities generated is very simple.

Impulsive tension.

For, calling the instantaneous speeds along the tangent and along the radius of absolute curvature $v_s$ and $v_\rho$ respectively, we have

$$\delta\mathrm{T}=\mu v_s\delta s,\qquad \mathrm{T}/\rho=\mu v_\rho,$$

where $\mu$ is the mass of unit length of chain at $s$. It is obvious that there can be no impulsive speed perpendicular to the osculating plane. The kinematical condition is simply that an elementary arc $\delta s$ is not altered in length. But the tangential increment of speed alone would imply an increase of the length of $\delta s$ in the ratio $1+\frac{dv_s}{ds}\delta t:1$ in time $\delta t$. Also the impulsive speed $v_\rho$ would imply a diminution of its length in the ratio $1-v_\rho\delta t/\rho:1$ by virtually making it an arc of a circle of smaller radius, but subtending the same angle at the centre. Hence, neglecting the square of $\delta t$ as compared with its first power, we find for the kinematical condition

$$\frac{dv_s}{ds}-\frac{v_\rho}{\rho}=0.$$

This gives, by eliminating the impulsive velocities,

$$\frac{d}{ds}\left(\frac{1}{\mu}\frac{d\mathrm{T}}{ds}\right)-\frac{1}{\mu}\frac{\mathrm{T}}{\rho^2}=0.$$

If the chain be uniform, this becomes

$$\frac{d^2\mathrm{T}}{ds^2}-\frac{\mathrm{T}}{\rho^2}=0.$$

The whole kinetic energy generated in the chain by the impulse is

$$\tfrac{1}{2}\int\frac{ds}{\mu}\left(\left(\frac{d\mathrm{T}}{ds}\right)^2+\frac{\mathrm{T}^2}{\rho^2}\right);$$

and the condition that this shall be a maximum is the differential equation above. This is a particular case of a general theorem due to Sir W. Thomson, viz.:—

*A material system of any kind, given at rest, and subjected to an impulse in any specified direction and of any given magnitude, moves off so as to take the greatest amount of kinetic energy which the specified impulse can give it.*

The direction in which an element of the chain begins to move is inclined to the tangent at an angle $\phi$ where

$$\tan\phi=\frac{v_\rho}{v_s}=\frac{\mathrm{T}}{\rho\frac{d\mathrm{T}}{ds}}.$$

270. It is to be observed that, in such questions as those just treated, the possibility of an impact's being propagated instantaneously along the whole length of a chain depends upon its assumed inextensibility. When a wire (such as that employed for a distance-signal on railways) is regarded as *extensible*, there is a definite speed with which a disturbance of the nature of extension is transmitted along it.

Waves of extension in a string.

Thus, recurring to the equations of § 267, we see that for the motion of a stretched elastic string in the direction of its length we have

$$\frac{d\mathrm{T}}{ds}=-\mu(\mathrm{X}-\ddot{x}).$$

If there be no applied forces, $\mathrm{X}=0$. Also, if we use $x$ instead of $s$ to characterize a particular point of the string, we must put $x+\xi$ for $x$ and $x$ for $s$, $\xi$ being a function of $x$ and $t$ which denotes at any instant the displacement of that point.

The physical condition is expressed by Hooke's Law in the form

$$E\frac{d\xi}{dx}=T$$

Hence
$$E\frac{d^2\xi}{dx^2}=\mu\ddot{\xi}.$$

This expresses (as in § 287) the passage of simultaneous waves. They are now waves of condensation and extension, not of transverse displacement. The nature of the interpretation of the equation is of the same general character as before, the speed being $\sqrt{E/\mu}$.

## Dynamics of an Elastic Solid.

§ 271. This subject, which is a very extensive and difficult one, and in its generality quite unsuitable for discussion here, has already been to some extent treated of under Elasticity. We therefore content ourselves with one or two examples, whose treatment is comparatively simple, while their applications are frequent and of considerable practical importance:

Cylindrical or prismatic wire, originally straight.

§ 272. Even so restricted a problem as that of determining the form assumed by a wire or thin rod of homogeneous isotropic elastic material, under the action of given forces and couples, presents somewhat formidable difficulties unless in its unstrained state the wire be straight and truly cylindrical or prismatic. And, even with these limitations, the problem again becomes formidable if we introduce the consideration of non-isotropic material; while, in any case, if the radius of curvature at each point is not very large in proportion to the thickness of the rod in the plane of bending, the problem is to no appreciable extent simplified by the limitation of form of the body. We will therefore give the comparatively simple case of the mere bending and twist of a homogeneous isotropic wire whose natural form is cylindrical or prismatic, the amounts of these from various sources being so small as to be superposable.

Bending. Twist.

Bending lengthens one set of lines of particles originally parallel to the axis of the wire and shortens others. Twist lengthens all but one such line, forming them into helices. The more detailed investigation, which we cannot give here, shows that there is one line of particles (the "elastic central line") which passes through the centre of inertia of each transverse section, and which may be treated (under our present limitations) as rigorously unchanged in length. The mutual molecular action of the parts of the wire on opposite sides of any transverse section may of course be reduced to a force and a couple, and the force may be conveniently treated as passing through the centre of inertia of the section. Also the twist and curvature of the wire near this section obviously depend on the couple and not on the force. For the moment of the couple is in general finite, while that of the force (about any point in the corresponding element of the wire) is infinitesimal.

§ 273. Let any two planes, at right angles to one another, be drawn through the elastic central line before distortion; and let them be cut in lines PR and PS by a transverse section through a point P of the central line. Also let PT be a tangent to that line. Suppose a similar construction to be carried out for every point P of the central line. Then it is clear that the form of the distorted wire will be completely determined if we know the form assumed by the central line, and the positions taken by the lines PR and PS drawn from each point in it. In their new positions P'T', P'R', and P'S' will still form (in consequence of the limitations we have imposed) a rectangular system; and the nature of the distortion will be clearly indicated by the change of position of this rectangular system as it passes from point to point of the distorted central line. The plane of rotation of P'T' is the osculating plane of the bending; its rate of rotation in that plane per unit length of the central line is the amount of bending; and the rate of rotation of the system P'R', P'S', about P'T', per unit length of the central line, is the rate of twist. Suppose P' to move with unit velocity along the distorted central line, and let $\rho$, $\sigma$, $\tau$ be the angular velocities of the system about P'R', P'S', P'T' respectively, then $\rho$ represents the curvature (or bending) resolved in the plane S'P'T', $\sigma$ that in R'P'T', while $\tau$ represents the twist.

Expressions for force and couple in terms of bending and twist.

Now, if the elastic forces constitute a conservative system, the amount of work done on an element of the body corresponding to a length $\delta s$ of the central line is to be calculated entirely from its change of form. It must therefore be expressible in the form

$$w\delta s$$

where $w$ is a function of $\rho$, $\sigma$, $\tau$; which must be such that the couples producing the bending are

$$\frac{dw}{d\rho} \text{ and } \frac{dw}{d\sigma}$$

while that producing the twist is

$$\frac{dw}{d\tau}.$$

These again are functions of $\rho$, $\sigma$, $\tau$, and they must, on account of the principle of superposition, be linear and homogeneous. For, within the limits to which we have restricted ourselves, the doubling alike of bending and twist must involve the doubling of each of the couples. Thus $w$ must be a homogeneous function of $\rho$, $\sigma$, $\tau$ of the second degree. Hence we may assume

$$w=\tfrac{1}{2}(A\rho^2+B\sigma^2+C\tau^2+2D\rho\sigma+2E\sigma\tau+2F\tau\rho),$$

where A, B, C, D, E, F are quantities depending on the form of the section of the wire and the nature of its material at each point. This gives

$$\frac{dw}{d\rho}=A\rho+D\sigma+F\tau,\quad \frac{dw}{d\sigma}=D\rho+B\sigma+E\tau,\quad \frac{dw}{d\tau}=F\rho+E\sigma+C\tau.$$

Hence, when the couples are assigned, the amounts of bending and twist are at once calculated from them. But the expression above is much more general than we require for the limited case we are considering. For, if the only couples applied to a portion of the prism or cylinder considered be in planes perpendicular to its length, twist only will be produced. Thus, for $\frac{dw}{d\rho}=0$, $\frac{dw}{d\sigma}=0$, we ought to have also $\rho=0$, $\sigma=0$. Hence E and F both vanish and we have simply

$$w=\tfrac{1}{2}(A\rho^2+2D\rho\sigma+B\sigma^2+C\tau^2).$$

This may be reduced, by properly selecting the planes originally drawn through the elastic central line, to the form

$$w=\tfrac{1}{2}(A\rho^2+B\sigma^2+C\tau^2).$$

Now we see that

$$\frac{dw}{d\rho}=A\rho,\ \frac{dw}{d\sigma}=B\sigma,\ \frac{dw}{d\tau}=C\tau.$$

§ 274. In a prismatic or cylindrical wire of homogeneous isotropic material, the elastic central line is thus a torsion axis simply. Equal and opposite couples, applied to the ends of such a wire, in planes perpendicular to its length, produce twist in direct proportion to the moments of the couples. There are two planes perpendicular to one another, and passing through this line, such that, if equal and opposite couples in either of these planes be applied at any parts of the wire, the portion between is bent into a circular arc in that plane. These are the principal planes of flexure. The quantities A and B which, when multiplied by the amount of bending in either of these planes, give the moment of the corresponding couple are called the principal "flexure rigidities" of the wire. When they are equal (as in the case of a wire of circular, square, equilateral triangular, &c., section) any plane through the axis is a principal plane of flexure. C is the torsional rigidity of the wire. In general, when the wire is fixed at one end and a couple applied at the other, the wire assumes the form of a circular helix. The exceptions (or rather particular cases) are:—(*a*) when the plane of the couple contains the elastic central line, and there is mere flexure, without twist; (*b*) when the plane of the couple is perpendicular to the wire, and there is twist simply.

Flexure rigidity. Torsional rigidity.

§ 275. As an example of the preceding theory, take firs

Flexure of plank by its own weight.

the case of a uniform plank clamped horizontally at one end, and otherwise unsupported. This is obviously the same as the case of a plank of double the length, supported by a trestle placed under its middle. We assume as before that the radius of curvature is always very large compared with the thickness of the plank.

In all such cases we may at once apply the principle of § 258, and suppose one portion of the plank up to a section P to be fixed in its equilibrium position. The curvature immediately contiguous to P will then be simply proportional to the moment about P of the forces acting on the unfixed portion. Hence at the free end there will be no curvature, and the curvature at points near that end will be of the second order of infinitesimals; *i.e.*, its rate of increase at the end vanishes.

Let $x$ be the length of the fixed portion, $l$ the whole length of the plank. Then, as the deflexion $y$ from the horizontal is always very small, the curvature is expressed (§ 22) by

$$\frac{d^2y}{dx^2},$$

so that we have at once

$$\mathrm{E}\frac{d^2y}{dx^2} = -\mu g\int_0^{l-x} x'dx' = -\tfrac{1}{2}\mu g(l-x)^2,$$

where E is the "flexural rigidity" of the plank, and $\mu$ its mass per unit of length.

Successive integrations give

$$\mathrm{E}\frac{dy}{dx} = \mathrm{B} + \tfrac{1}{6}\mu g\,(l-x)^3,$$

and

$$\mathrm{E}y = \mathrm{A} - \mathrm{B}(l-x) - \tfrac{1}{24}\mu g(l-x)^4.$$

The terminal conditions are

for $x=0$ $\qquad y=0, \quad \dfrac{dy}{dx}=0$

and for $x=l$, $\qquad \dfrac{d^2y}{dx^2}=0, \quad \dfrac{d^3y}{dx^3}=0$

The last two are obviously satisfied.

The two former give

$$\mathrm{B} = -\frac{\mu g l^3}{6}, \quad \mathrm{A} = \mathrm{B}l + \tfrac{1}{24}\mu g l^4 = -\tfrac{1}{8}\mu g l^4.$$

Hence

$$\mathrm{E}y = -\tfrac{1}{24}\mu g(3l^4 - 4l^3(l-x) + (l-x)^4).$$

Thus the droop of the free extremity ($x=l$) is

$$\frac{\mu g}{8}\frac{l^4}{\mathrm{E}} = \frac{\mathrm{W}l^3}{8\mathrm{E}},$$

where W is the whole weight.

If the plank had been weightless, but loaded at the free end with a weight W, our equation would have been

$$\mathrm{E}\frac{d^2y}{dx^2} = -\mathrm{W}(l-x),$$

and we should have had

$$\mathrm{E}\frac{dy}{dx} = \mathrm{B}' + \tfrac{1}{2}\mathrm{W}(l-x)^2,$$

$$\mathrm{E}y = \mathrm{A}' - \mathrm{B}'(l-x) - \tfrac{1}{6}\mathrm{W}(l-x)^3.$$

The terminal conditions at $x=0$ are as before, so that

$$\mathrm{B}' = -\tfrac{1}{2}\mathrm{W}l^2, \quad \mathrm{A}' = -\tfrac{1}{2}\mathrm{W}l^3 + \tfrac{1}{6}\mathrm{W}l^3 = -\tfrac{1}{3}\mathrm{W}l^3,$$

and the droop of the free end is $\dfrac{\mathrm{W}l^3}{3\mathrm{E}}$, greater than before in the ratio of 8 : 3.

If the plank be again looked on as heavy, but its free end be supported on a trestle which is pressed upwards till it acts with a force W we find directly

$$\mathrm{E}\frac{d^2y}{dx^2} = \mathrm{W}(l-x) - \tfrac{1}{2}\mu g(l-x)^2,$$

$$\mathrm{E}\frac{dy}{dx} = \mathrm{B}'' - \tfrac{1}{2}\mathrm{W}(l-x)^2 + \tfrac{1}{6}\mu g(l-x)^3,$$

$$\mathrm{E}y = \mathrm{A}'' - \mathrm{B}''(l-x) + \tfrac{1}{6}\mathrm{W}(l-x)^3 - \tfrac{1}{24}\mu g(l-x)^4.$$

The terminal conditions, at $x=0$, are still as in the first case, and they give

$$\mathrm{B}'' = \tfrac{1}{2}\mathrm{W}l^2 - \tfrac{1}{6}\mu g l^3,$$

when the amount by which the free end is raised is

$$\frac{\mathrm{A}''}{\mathrm{E}} = [l(\tfrac{1}{2}\mathrm{W}l^2 - \tfrac{1}{6}\mu g l^3) - \tfrac{1}{6}\mathrm{W}l^3 + \tfrac{1}{24}\mu g l^4] / \mathrm{E} = \frac{5\mathrm{W}l^3}{24\mathrm{E}}.$$

This is obviously the same as the amount of depression of the middle of a plank of length $2l$ supported by trestles at each end.

§ 276. Hence the droop of the middle of a plank resting on trestles at its ends is to that of the ends when the plank rests on a single trestle at the middle in the ratio of 5 : 3.

If the equation expressing the curvature in the first or third cases above be twice differentiated, the common result is

$$\mathrm{E}\frac{d^4y}{dx^4} = -\mu g.$$

Horizontal plank under any vertical forces.

The simplicity of this expression leads us to seek for the most general form. Suppose the plank to be exposed to any system of forces in lines perpendicular to its length and breadth. Then, if any transverse section be made, the stress between the two portions of the plank will consist of forces ($\pm$G) and couples ($\pm$H) in the plane of length and thickness. Let the applied forces be N per unit of length. Suppose also, as before, that the radius of curvature is very great compared with the thickness. Then the equations of equilibrium of an element are

$$\frac{d\mathrm{G}}{dx} + \mathrm{N} = 0, \quad \frac{d\mathrm{H}}{dx} + \mathrm{G} = 0$$

We have also the condition of bending, viz.,

$$\mathrm{E} \times \text{curvature} = \mathrm{E}\frac{d^2y}{dx^2} = \mathrm{H}.$$

Eliminating H and G among these equations, we have

$$\mathrm{E}\frac{d^4y}{dx^4} = \frac{d^2\mathrm{H}}{dx^2} \qquad \frac{d\mathrm{G}}{dx} = \mathrm{N},$$

which of course includes all the previous particular cases. We may now determine (under the limits imposed) the form of a uniform plank of any length, supported in a nearly horizontal position at different points in its length, and loaded at any assigned points with any weights. The importance of this in practice is obvious.

Vibration of plank or flat spring.

§ 277. But we may easily take a further step, and investigate the oscillatory motion, so long at least as the acceleration parallel to the length of the plank and its rotation are negligible. For in such a case, if $\mu$ be the mass per unit of length, the equation of motion is (§ 199)

$$\mathrm{E}\frac{d^4y}{dx^4} = \mathrm{N} - \mu\ddot{y}.$$

We will consider only the case in which the applied force N may be neglected. This is practically the case of a uniform wire or flat rectangular spring. Suppose, further, that it is fixed at one end and free at the other, like Wheatstone's "kaleidophone," or like the tongue of a reed organ-pipe.

Then, writing $n^4$ for the fraction $\mu/\mathrm{E}$, we have

$$\frac{d^4y}{dx^4} + n^4y = 0.$$

A particular integral may obviously be found in the form

$$y = \eta\cos(i^2l/n^2 + \alpha) \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (1),$$

where $\eta$ (a function of $x$) and $i/n$ (a constant number) have to be found; $\alpha$ is any constant. The substitution of this value of $y$ leads to

$$\frac{d^4\eta}{dx^4} - i^4\eta = 0,$$

the complete integral of which is

$$\eta = \mathrm{A}\varepsilon^{ix} + \mathrm{B}\varepsilon^{-ix} + \mathrm{C}\cos(ix + \mathrm{D}).$$

Now, provided the value of $i$ be properly determined, the motion represented by (1), with the above value of $\eta$, can exist by itself; and the most general motion of which the spring is capable (under the limits imposed) consists of superposition of a number of separate motions of a similar character. Hence this may be treated by itself. Our limiting conditions in the present case are

$x=0$, $\qquad \eta=0, \ \dfrac{a\eta}{dx}=0$ at the fixed end;

and $x=l$, $\qquad \dfrac{d^2\eta}{dx^2}=0, \ \dfrac{d^3\eta}{dx^3}=0$ at the free end.

Now, from the value of $\eta$ above, we have

$$\frac{1}{i}\frac{d\eta}{dx} = Ae^{ix} - Be^{-ix} - C\sin(ix+D),$$

$$\frac{1}{i^2}\frac{d^2\eta}{dx^2} = Ae^{ix} + Be^{-ix} - C\cos(ix+D),$$

$$\frac{1}{i^3}\frac{d^3\eta}{dx^3} = Ae^{ix} - Be^{-ix} + C\sin(ix+D).$$

Hence we have

$$\begin{aligned} 0 &= A + B + C\cos D, \\ 0 &= A - B - C\sin D, \\ 0 &= Ae^{il} + Be^{-il} - C\cos(il+D), \\ 0 &= Ae^{il} - Be^{-il} + C\sin(il+D). \end{aligned}$$

Eliminating C and D, we have

$$\begin{aligned} 0 &= Ae^{il} + Be^{-il} + (A+B)\cos il + (A-B)\sin il, \\ 0 &= Ae^{il} - Be^{-il} - (A+B)\sin il + (A-B)\cos il. \end{aligned}$$

Eliminate the ratio A/B, which is all that these equations furnish and we have

$$(e^{il} + e^{-il})\cos il + 2 = 0.$$

From this equation the values of $i$ must be determined. It is clear that the multiplier of $\cos il$ is always greater than 2, except in the special case of $i=0$, which we obviously need not consider, as it gives $y=0$, and therefore belongs to the statical problem already considered. Hence as, to make $\cos il$ negative, $il$ must be greater than $\frac{1}{2}\pi$; and, as $e^{\frac{1}{2}\pi} + e^{-\frac{1}{2}\pi} = 5$ nearly, it is clear that the excess of the first value of $il$ over $\frac{1}{2}\pi$ is somewhere about 0·3. The next value falls short of $\frac{3}{2}\pi$ by a quantity of the order $\frac{1}{100}$, the next exceeds $\frac{5}{2}\pi$ by a quantity of the order $\frac{1}{2500}$, &c. The required values arrange themselves in two groups, one of either group being taken alternately. The first group involves arcs a little greater than but rapidly approaching to the values of $(4m+1)\frac{1}{2}\pi$; the second consists of arcs a little less than but rapidly approaching to those of $(4m+3)\frac{1}{2}\pi$.

Effects of pressure on tubes and spherical shells.

§ 278. Some of the simplest, but at the same time most practically useful, of questions connected with elasticity of solids relate to the changes of form or volume experienced by circular cylindrical tubes or spherical shells exposed to hydrostatic pressure. A steam-boiler, the cylinders and tubes of an hydraulic press, a fowling-piece or cannon and (on a much smaller scale) Örsted's piezometer, deep-sea thermometers, &c., afford common instances. All that is necessary for attacking such questions is given in §§ 45, 46 of the article ELASTICITY. For it is there shown that, if a homogeneous isotropic elastic solid be subjected to a simple longitudinal stress P, uniform and in a definite direction throughout its whole substance, the result will be linear extension $= P\left(\frac{1}{3n} + \frac{1}{9k}\right)$ in the direction of P, and linear contraction $= P\left(\frac{1}{6n} - \frac{1}{9k}\right)$ in all directions perpendicular to P. The quantities $n$ and $k$, as explained in the article referred to, are respectively the "rigidity" and the reciprocal of the "compressibility" of the solid operated on.

Equal pressures within and without piezometer.

§ 279. The case of the piezometer, in which the vessel holding the liquid whose compression is to be measured is exposed both inside and outside to the same hydrostatic pressure, is seen to correspond to three equal stresses in directions at right angles to one another. These directions may be any whatever, and in each of them the linear extension is obviously

$$P\left\{\left(\frac{1}{3n} + \frac{1}{9k}\right) - 2\left(\frac{1}{6n} - \frac{1}{9k}\right)\right\} = \frac{P}{3k}.$$

P is negative, as the stress is a pressure. Hence the strain consists in a simple alteration of volume measured by $P/k$. Every part of the walls of the vessel, as well as its external bulk, and its interior content, is altered to the same extent.

Cylinder under internal pressure.

§ 280. In the case of a cylinder, when the internal and external pressures are different, it is clear from symmetry that the stresses may be resolved at any point of the walls into three at right angles to one another, the first ($P_1$) parallel to, the second ($P_2$) at right angles to, the axis, and the third ($P_3$) perpendicular to each of the other two. In a transverse section of the cylinder, the second of these is radial and the third is tangential to a coaxal cylinder passing through the element considered. We suppose the cylinder closed at both ends, and we make the further assumption (quite exact enough for practical applications, and most important from the point of view of simplicity of calculation) that all transverse sections of the cylinder remain, after distortion, transverse sections. This is equivalent to assuming $P_1$ to be constant throughout the walls of the cylinder. Hence, if there be interior pressure only, the value of this stress must be

$$P_1 = \frac{\text{pressure on end of interior of cylinder}}{\text{area of transverse section of walls of cylinder}} = \frac{\Pi a_0^2}{a_1^2 - a_0^2},$$

where $\Pi$ is the interior hydrostatic pressure, and $a_0$, $a_1$ are the internal and external radii. This stress represents a longitudinal *tension* of the walls of the cylinder.

Let us consider an element of the cylindrical wall, defined as follows in the unstrained state:—

Draw two transverse sections at distances $x$ and $x+\delta x$ from one end, two planes through the axis making an (infinitesimal) angle $\theta$ with one another, and two cylinders of radii $r$ and $r+\delta r$ about the common axis. In the strained state $\theta$ is unchanged, but $x$ becomes $x+\xi$, and $r$ becomes $r+\rho$. The distance between the transverse sections was $\delta x$; it becomes $\delta x + \frac{d\xi}{dx}\delta x$, so that the linear extension parallel to the axis is $\frac{d\xi}{dx}$. The distance between the cylinders was $\delta r$; it becomes $\delta r + \frac{d\rho}{dr}\delta r$, so that the radial extension is $\frac{d\rho}{dr}$. The breadth of the base of the wedge-shaped element was $r\theta$; it becomes $(r+\rho)\theta$, so that the linear extension perpendicular alike to the radial line and to the axis is $\frac{\rho}{r}$

If we now write, for simplicity,

$$e = \frac{1}{3n} + \frac{1}{9k}, \quad f = \frac{1}{6n} - \frac{1}{9k},$$

the three requisite equations between stresses and strains are at once obvious in the form

$$\begin{aligned} \frac{d\xi}{dx} &= eP_1 - fP_2 - fP_3, \\ \frac{d\rho}{dr} &= -fP_1 + eP_2 - fP_3, \\ \frac{\rho}{r} &= -fP_1 - fP_2 + eP_3. \end{aligned}$$

We have, however, four unknown quantities $\xi$, $\rho$, $P_2$, and $P_3$, so that another equation is required. This must be supplied by one of the statical conditions of equilibrium of the element above defined, when in its strained state. There is obviously equilibrium in the axial direction, and also parallel to the base of the element; but radially we have a case resembling that of an element of a cord as in § 264. Neglecting small quantities of a higher order than those retained, this consideration gives

$$P_3\delta\theta\delta x\delta r = \frac{d}{dr}(P_2 r\delta\theta\delta x)\delta r, \quad \text{or} \quad P_3 = \frac{d}{dr}(P_2 r).$$

Solving the four equations, and taking account of the boundary conditions

$$P_2 = -\Pi \text{ when } r = a_0, \text{ and } P_2 = 0 \text{ when } r = a_1,$$

we obtain the following values:—

$$\frac{d\xi}{dx} = \Pi\frac{a_0^2}{a_1^2 - a_0^2}(e - 2f),$$

$$\frac{\rho}{r} = \Pi\frac{a_0^2}{a_1^2 - a_0^2}\left[(e-2f) + \frac{a_1^2}{r^2}(e+f)\right],$$

$$\frac{d\rho}{dr} = \Pi\frac{a_0^2}{a_1^2 - a_0^2}\left[(e-2f) - \frac{a_1^2}{r^2}(e+f)\right].$$

or, reintroducing the values of $e$ and $f$,

$$\frac{d\xi}{dx} = \frac{\Pi a_0^2}{a_1^2 - a_0^2}\frac{1}{3k},$$

$$\frac{\rho}{r} = \frac{\Pi a_0^2}{a_1^2 - a_0^2}\left(\frac{1}{3k} + \frac{a_1^2}{r^2}\frac{1}{2n}\right),$$

$$\frac{d\rho}{dr} = \frac{\Pi a}{a_1^2 - a_0^2}\left(\frac{1}{3k} - \frac{a_1^2}{r^2}\frac{1}{2n}\right).$$

§ 281. Thus the nature of the distortion produced in the walls of a cylindrical tube by internal pressure may be described as made up

of a uniform dilatation, whose linear measure in every direction is $\frac{\Pi a_0^2}{a_1^2 - a_0^2}\frac{1}{3k}$, combined with a shear in each transverse section, whose measure is $1 \pm \frac{\Pi a_0^2 a_1^2}{(a_1^2 - a_0^2)r^2}\frac{1}{2n}$. § 91.

The shorter axis of this shear is radial, and the magnitude of the shear is obviously greater for smaller values of $r$. The inner layer of the walls is thus the most distorted. The amount of the distortion is directly as the pressure, and inversely as the area of the section of the walls.

When the walls are very thin the shear is practically the same throughout their thickness. When they are very thick, the shear near the inner surface is nearly $1 \pm \frac{\Pi}{2n}$, however fine be the bore.

That near the outer surface is nearly $1 \pm \frac{a_0^2}{a_1^2}\frac{\Pi}{2n}$, which vanishes when the bore is very fine. Thus it appears that, if a stout tube bursts by the shear produced by internal pressure, little is gained either by making it of extremely great thickness or by making it of very small bore.

The diagrams A and B in fig. 66 show, necessarily on a greatly exaggerated scale, the nature of the distortion produced at different

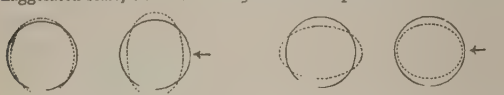

Fig. 66.

parts of the wall of the tube. They represent transverse sections of small, originally spherical, elements made by planes at right angles to the axis. The radial diameters are horizontal. A is an element close to the external surface, B an element near the inner surface. The increase per unit volume of the interior of the tube is

$$\frac{\Pi a_0^3}{a_1^3 - a_0^3}\left(\frac{1}{k} + \frac{a_1^3}{a_0^3}\frac{1}{n}\right);$$

so that, if the tube be very thick in comparison with its bore, the increase is nearly $\Pi/n$. In flint glass this is approximately about $\frac{1}{1000}$, when $\Pi$ is a ton-weight per square inch.

Cylinder under external pressure.

§ 282. The reader who has followed the above investigation will find no difficulty in obtaining the corresponding results for a cylindrical tube, closed at both ends and exposed to external pressure $\Pi$, in the form

$$\frac{d\xi}{dx} = -\frac{\Pi a_1^2}{a_1^2 - a_0^2}\frac{1}{3k},$$

$$\frac{\rho}{r} = -\frac{\Pi a_1^2}{a_1^2 - a_0^2}\left(\frac{1}{3k} + \frac{a_0^2}{r^2}\frac{1}{2n}\right),$$

$$\frac{d\rho}{dr} = -\frac{\Pi a_1^2}{a_1^2 - a_0^2}\left(\frac{1}{3k} - \frac{a_0^2}{r^2}\frac{1}{2n}\right).$$

The only comments we need make are (1) that the signs of these distortions are now negative; (2) that they are (so far as change of volume is concerned) greater than for the internal pressure, as $a_1^3$ has taken the place of $a_0^3$ as a factor in each term involving $k$; (3) that the terms involving the rigidity are, except as regards sign, unchanged.

The change of volume of every part of the walls is

$$-\frac{\Pi a_1^3}{a_1^3 - a_0^3}\frac{1}{k},$$

and the change of volume of the interior is

$$\frac{\Pi a_1^3}{a_1^3 - a_0^3}\left(\frac{1}{k} + \frac{1}{n}\right)$$

The numerical value of the factor $\Pi\left(\frac{1}{k} + \frac{1}{n}\right)$ is about $\frac{1}{1000}$ for flint glass and about $\frac{1}{10000}$ for steel, when $\Pi$ is a ton-weight per square inch. There is, however, a peculiarity which (when the walls are thick enough) distinguishes this from the preceding case. For $k$ is usually considerably greater than $n$, so that *a fortiori* $3k$ is greater than $2n$. Hence, in the value of $d\rho/dr$, the term in $n$ is always greater than that in $k$ so long as the pressure is internal. Thus the radial effect is compression at all parts of the walls. But, when the pressure is external, we may (if the walls be thick enough) find a value of $r$ for which

$$\frac{1}{3k} = \frac{a_0^2}{r^2}\frac{1}{2n}.$$

In glass, this occurs when $r = 1{\cdot}6a_0$ nearly. At this distance from the axis there is no radial change of length; at greater distances there is radial compression, and at smaller radial extension. This is indicated in the diagrams C and D in fig. 66, which like the former are greatly exaggerated. They represent the distortion of small spherical elements of a thick tube,—the first at the inner wall, the second at the outer surface. As before, these are sections made by a plane perpendicular to the axis of the cylinder.

Spherical shell under external pressure.

§ 283. In a spherical shell of internal and external radii $a_0$ and $a_1$, the equations become a little more simple on account of the more complete symmetry.

Using the same notation, so far as it is now applicable, we have

$$\frac{d\rho}{dr} = -2fP_1 + eP_2, \qquad \frac{\rho}{r} = (e-f)P_1 - fP_2.$$

The statical equation is

$$2rP_1 = \frac{d}{dr}(r^2 P_2).$$

With these we obtain, for external pressure $\Pi$, the result

$$\frac{\rho}{r} = -\Pi\frac{a_1^3}{a_1^3 - a_0^3}\left(\frac{1}{3k} + \frac{a_0^3}{r^3}\frac{1}{4n}\right),$$

from which the other equation may be derived by differentiation.

§ 284. The propagation of plane waves in an elastic solid has been discussed in ELASTICITY, and the mechanics of fluids is discussed under HYDROMECHANICS.

## GENERAL CONSIDERATIONS.

General considerations.

§ 285. The preceding view of the subject of Abstract Dynamics has been based entirely upon Newton's Laws of Motion, which were adopted without discussion, as a complete and perfectly definite foundation; and the terms employed, as well as the mode of treatment in general, have somewhat closely followed Newton's system. The only considerable apparent departure from that system is connected with the development of the idea of energy, and its application to the simplification of many of the methods and results. This also was, as we have seen, really introduced by Newton; but it has been immensely extended since his time both by mathematical and by experimental processes. It is time that we should now return to the laws of motion, and examine more closely, in the light of what we have learned, one or two of the more prominent ideas which they embody. To do so fairly we must go back to Newton's own definitions of the terms which he employs. About many of these, which have already been quoted in §§ 97–113, there is no difference of opinion. But it is otherwise when we come to the definition of "force" (§§ 5, 104).

Force.

There can be no doubt that the proper use of the term "force" in modern science is that which is implied in the statement of the first law of motion, as we rendered it in § 1 from Newton's Latin. It is thus seen to be the English equivalent of the term *vis impressa*. Newton uses the word *vis* in other connexions, and with a certain vagueness inevitable at a time when the terminology of science was still only shaping itself; but his idea of "force" was perfectly definite, and when *this* is in his mind the vague word *vis* is (when necessary) always qualified and rendered precise, either by the addition of *impressa* or in some equally unambiguous way. To render *vis* by "force," wherever it stands without the *impressa* or its equivalents, is to introduce a quite gratuitous confusion for which Newton is not responsible. We have only to think of the multitude of terms, such as *vis insita* (inertia), *vis acceleratrix* (acceleration), *vis viva* (kinetic energy), &c., &c., to see that all such complex expressions must be regarded as *wholes*, and that *vis* does not mean "force" in any one of them.

§ 286. Thus in Newton's view *force is whatever changes* (but not "*or tends to change*") *a body's state of rest or of uniform motion in a straight line.*

He mentions, as instances, percussion, pressure, and central force.[1] Under the last of these heads he expressly includes magnetic as well as gravitational force. Thus

[1] *Vis centripeta.* It has been already explained that such word as *centripeta* include *impressa*, so that the above rendering of Newton' phrase is the obvious one

force may have different origins, but it is always one and the same; and it produces, in any body to which it is applied, a change of momentum in its own direction, and in amount proportional to its magnitude and to the time during which it acts.

§ 287. Thus, from Newton's point of view, equilibrium is not a balancing of forces, but a balancing of the effects of forces. When a mass rests on a table, gravity produces in it a vertically downward velocity which is continually neutralized by the equal upward velocity produced by the reaction of the table; and these forces, whose origins and places of application are alike so widely different, are (as forces), in every respect except direction, similar and equal. And they are so because they produce, in equal times, equal and opposite quantities of motion.

Origin of the idea of force.

§ 288. The idea of "force" was undoubtedly suggested by the "muscular sense"; and there can be no question as to the vividness of the sensation of effort we experience when we try to lift a heavy weight or to open a massive gate. In this, as in other cases, it is the business of science to find what objective fact corresponds to the subjective data of sensation. It is very difficult to realize the fact, certain as it is, that light (in the sense of *brightness*) is a mere sensation or subjective impression, and has no objective existence. Yet we know that, beside those radiations which give us the sensation of light, there are others, in endless series both higher and lower in their refrangibility, to which our eyes are absolutely blind. And the only difference between these and the former is one of mere wave-length or of period of vibration. Similarly, it is very hard to realize the fact that sound (in the sense of *noise*) is only a sensation; and that outside us there is merely a series of alternate compressions and dilatations of the air, the great majority of which produce no sensible effect upon our ears. Thus because we know that we should seek in vain for brightness or noise in the external world, familiar as our senses have rendered us with these conceptions, we are driven to inquire whether the idea of *force* may not also be a mere suggestion of sense, corresponding (no doubt) to some process going on outside us, but quite as different from the sensation which suggests it as is a periodic shearing of the ether from brightness, or a periodic change of density of air from noise.

§ 289. So far, we have treated of force as acting on a body without inquiring whence or why; we have referred to the first and second laws of motion only, and have thus seen only one half of the phenomenon. As soon, however, as we turn to the third law, we find a new light cast on the question. Force is always dual. To *every* action there is *always* an equal and contrary reaction. Thus the weight which we lift or try to lift, and the massive gate which we open or try to open, both as truly exert force upon our hands as we do upon them. This looking to the other side of the account, as it were, puts matters in a very different aspect. "Do you mean to tell me," said a medical man of the old school, "that, if I pull a 'subject' by the hand, it will pull me with an equal and opposite force?" When he was convinced of the truth of this statement, he gave up the objectivity of force at once.

§ 290. The third law, in modern phraseology, is merely this:—

*Every action between two bodies is a stress.*

When we pull one end of a string, the other end being fixed, we produce what is called *tension* in the string. When we push one end of a beam, of which the other end is fixed, we produce what is called *pressure* throughout the beam. Leaving out of account, for the moment, the effects of gravity, this merely amounts to saying that there is stress across every transverse section of the string or beam. But, in the case of the string, the part of the stress which every portion exerts on the adjoining portion is a *pull*; in the case of the beam it is a *push*. And all this distribution of stress, though exerted across every one of the infinitely numerous cross sections of the string or beam, disappears the moment we let go the end. We can thus, by a touch, call into action at will an infinite number of stresses, and put them out of existence again as easily. This, of itself, is a very strong argument against the supposition that force, in any form, can have objective reality.

Objective physical realities.

§ 291. We must now say a word or two on the question of the objective realities in the physical world. If we inquire carefully into the grounds we have for believing that matter (whatever it may be) has objective existence, we find that by far the most convincing of them is what may be called the "conservation of matter." This means that, do what we will, we cannot alter the mass or quantity of a portion of matter. We may change its form, dimensions, state of aggregation, &c., or (by chemical processes) we may entirely alter its appearance and properties, but its quantity remains unchanged. It is this experimental result which has led, by the aid of the balance, to the immense developments of modern chemistry. If we receive this as evidence of the objective reality of matter, we must allow objective reality to anything else which we find to be conserved *in the same sense* as matter is conserved Now there is no such thing as negative mass; mass is, in mathematical language, a signless quantity. Hence the conservation of matter does not contemplate the simultaneous production of equal quantities of positive and negative mass, thus leaving the (algebraic) sum unchanged. But this is the nature of conservation of momentum (§ 165) and of moment of momentum. The only other known thing in the physical universe, which is conserved in the same sense as matter is conserved, is energy. Hence we naturally consider energy as the other objective reality in the physical universe, and look to it for information as to the true nature of what we call force.

True nature of force.

§ 292. When we do so, the answer is easily obtained, and in a completely satisfactory form. We give only a very simple instance. When a stone, whose mass is M and weight W, has fallen through a space $h$ towards the earth, it has acquired a speed $v$, which (§ 28) is given by the equation

$$\tfrac{1}{2}Mv^2 = Wh.$$

This is a particular case of the conservation of energy, but the terms in which it is expressed are those suggested by Newton's laws of motion, and are therefore based on the recognition of "force." The first member of the equation represents the kinetic energy acquired; the second the potential energy lost, or the work done by gravity upon the stone during its fall. Both members therefore express real things, having objective existence.

Space-rate of transformation of energy.

But the "force" (so-called) which is said to have produced the motion, has the value

$$W = \tfrac{1}{2}Mv^2/h,$$

*i.e.*, it is the *rate per unit of length*, at which potential energy is converted into kinetic energy during the fall. In other words, it is merely an expression for the *space-rate at which energy is transformed.*

§ 293. Another mode of presenting the case will make this still more clear. The average speed with which the stone falls is (§ 28) $v/2$. Divide both sides of the equation above by this quantity, remembering that $2h/v$ is the time of falling, which we call $t$. We have thus, as another perfectly legitimate deduction from our premises,

Time-rate of change of momentum.

$$W = Mv/t.$$

Here the (so-called) force appears in a new light. It is now the *time-rate at which momentum is generated* in the falling stone.

§ 294. The statements in the last two sections are, in fact, merely particular cases of Newton's two interpretations of action in the third law, which have already been discussed (§§ 165, 167).

Analytically, the whole affair is merely this: if $s$ be the space described, $v$ the speed of a particle,

$$\ddot{s}=\dot{v}=\frac{dv}{dt}=\frac{dv}{ds}\cdot\frac{ds}{dt}=v\frac{dv}{ds}.$$

Hence the equation of motion (formed by the second law)

$$m\ddot{s}=m\dot{v}=f,$$

which gives $f$ as the time-rate of increase of momentum, may be written in the new form

$$mv\frac{dv}{ds}=\frac{d}{ds}(\tfrac{1}{2}mv^2)=f,$$

giving $f$ as the space-rate of increase of kinetic energy.

Rate.

§ 295. But a mere *rate*, be it a space-rate or a time-rate, is not a thing which has objective existence. No one would confound the bank rate of interest with a sum of money, nor the birth or death rate of a country with a group of individual human beings. These rates are, in fact, mere abstract numbers, by the help of which a man may compute interest per annum from the amount of capital, or the number of infants per annum from the amount of the population. The gradient of temperature, in an irregularly heated body, is a mere vector-rate, by the help of which we can calculate how much energy (in the form of heat) passes in a given time across any assigned surface in the body. To attribute objectivity to a rate is even more ridiculous than it would be to attribute it to a sensation, or to a thought, or to a word or phrase which we find useful in characterizing some material object.

§ 296. On the other hand, all these different kinds of rates have been introduced and continue to be employed, because they have been found to be useful. There is no harm done by retaining them, provided those who use them know that they are introduced for convenience of expression, and not because there are objective realities corresponding to them. Even such a term as "centrifugal force" is sometimes useful; but always under the proviso that he who employs it shall remember that it is only one side of the stress under which a particle of matter is compelled, in spite of its inertia, to move in a curved line. But the term must be taken, like "algebra," "theodolite," "Abracadabra," or any other combination of letters whose derivation is uncertain or unknown, as one and indivisible, to which a certain definite meaning is attached, and as having nothing whatever to do with the meaning or derivation of the word centrifugal, whose embodiment in it is a perennial monument to the memory of an old error.

Potential energy kinetic.

§ 297. The main characteristics of energy, especially from the experimental point of view, have already been discussed under DYNAMICS (*q.v.*) and ENERGY (*q.v.*). But there is one point of importance connected with it which comes more naturally here than in either of the articles referred to.

When two measurable quantities, of any kind, are equivalent to one another, their numerical expressions must involve the same fundamental units, and in the same manner. This is obvious from the fact that an alteration of any unit alters in the inverse ratio the numerical measure of any quantity which is a mere multiple of it. And equivalent quantities must always be expressed by equal numbers when both are measured in terms of the same system of units. It appears, therefore, from the conservation of energy directly, as well as from the special data in §§ 111, 113, that potential energy must, like kinetic energy, be of dimensions $[ML^2T^{-2}]$.

Now it is impossible to conceive of a truly dormant form of energy whose magnitude should depend in any way on the unit of time; and we are therefore forced to the conclusion that potential energy, like kinetic energy, depends (in some as yet unexplained, or rather unimagined, way) upon motion. For the immediate purposes of this article the question is not one of importance. We have been dealing with the more direct consequences of a very compact set of laws, exceedingly simple in themselves, originally based upon observation and experiment, and, most certainly, true. But reason cannot content itself with the mere consequences of a series of observed facts, however elegantly and concisely these may be stated by the help of new terms and their definitions. We are forced to inquire into what may underlie these definitions, and the laws which are observed to regulate the things signified by them. And the conclusion which appears inevitable is that, whatever matter may be, the other reality in the physical universe, energy, which is never found unassociate with matter, depends in all its widely varied forms upon motion of matter. In some cases we are sure, in others we can as yet only suspect, that it depends upon motions in a medium which, unlike ordinary matter, has not yet been subjected to the scrutiny of the chemist. But the question, in its generality, is one of the most obscure in the whole range of physics. In the articles ATOM, ATTRACTION, ETHER, will be found nearly all that is yet known on this profoundly difficult subject. But to what is there said must be added the remark that a state of strain of the ether, whether associated with the propagation of light and radiant heat or with a statical distribution of electricity, represents so much "potential" energy, and must in its turn in some way depend on motion.

Maxwell on inertia.

§ 298. The remarks of Clerk Maxwell on the nature of the evidence for Newton's *first* law of motion raise a question, in some respects novel, but in all respects well worthy of careful study. He says:—

"Our conviction of the truth of this law may be greatly strengthened by considering what is involved in a denial of it. Given a body in motion. At a given instant let it be left to itself and not acted on by any force. What will happen? According to Newton's law it will persevere in moving uniformly in a straight line; that is, its velocity will remain constant both in direction and magnitude.

"If the velocity does not remain constant let us suppose it to vary. The change of velocity must have a definite direction and magnitude. By the maxim that *the same causes will always produce the same effects*, this variation must be the same whatever be the time or place of the experiment. The direction of the change of motion must therefore be determined either by the direction of the motion itself, or by some direction fixed in the body. Let us, in the first place, suppose the law to be that the velocity diminishes at a certain rate, which, for the sake of the argument, we may suppose so slow that by no experiments on moving bodies could we have detected the diminution of velocity in hundreds of years. The velocity referred to in this hypothetical law can only be the velocity referred to a point absolutely at rest. For if it is a relative velocity, its direction as well as its magnitude depends on the velocity of the point of reference. If, when referred to a certain point, the body appears to be moving northward with diminishing velocity, we have only to refer it to another point moving northward with a uniform velocity greater than that of the body, and it will appear to be moving southward with increasing velocity. Hence the hypothetical law is without meaning, unless we admit the possibility of defining absolute rest and absolute velocity. . . . .

"It may thus be shown that the denial of Newton's law is in contradiction to the only system of consistent doctrine about space and time which the human mind has been able to form."

Principle of sufficient reason.

This is a good example of a valuable application of a principle which, in its widest scope, is inconsistent with the true foundations of physical science. It is, in fact, the exceedingly dangerous "principle of sufficient reason"—which requires for its legitimate use the utmost talent and knowledge on the part of the user.

True laws of motion.

§ 299. But in all methods and systems which involve the idea of force there is the leaven of artificiality. *The* true laws of motion, based entirely on experiments of the most extensive and most varied kinds, are those of the conservation and of the transformation of energy. With the help

of kinematical ideas, it is easy to base the whole science of dynamics on these principles; and there is no necessity for the introduction of the word "force" nor of the sense-suggested ideas on which it was originally based.

§ 300. Nothing beyond a mere mention has been made above of virtual velocities, and of the so-called elementary machines. These belong to the subject of Applied Mechanics, separately treated below.

§ 301. The references which have been made to various grand theories, such as action, impulse in general, &c., have been illustrated by simple cases only. For a detailed examination of these theories the reader is referred to Thomson and Tait's *Natural Philosophy*, chap. ii. To the same work he is referred for the general "theory of small oscillations," the "dissipative function," the "ignoration of coordinates," the treatment of "gyrostatic systems" and of "kinetic stability." All of these have been exhibited, though in mere particular instances, in the preceding pages.

*Treatises on Mechanics.*

§ 302. The following works on Mechanics are indispensable:—

1. Newton's *Principia* (1st ed., 1687; latest ed., Glasgow, 1871). Here, for the first time, the fundamental principles were systematized, extended (as we have seen) in a most vital particular, and applied, by the aid of a new mathematical method of immense power (based entirely on kinematical considerations), to many of the most important questions of cosmical and terrestrial dynamics.

Newton's system was first *taught* in the university of Edinburgh; and, with brief intervals, his methods also have been habitually kept before the students there. From the time of Maclaurin to that of Forbes the value of the quasi-geometrical methods in giving a clear insight into the problems treated has rarely been overlooked. In Cambridge these methods were of later introduction, but they still deservedly figure as a necessary part of the reading of candidates for "mathematical honours." It is to be feared, however, that in some other British universities the study of Newton's methods is not prosecuted to anything like the same extent. But the very reverse seems to be the case in America, where, probably to a considerable extent on this account, mathematical physics is advancing in a most remarkable manner.

2. Lagrange's *Mécanique Analytique* (1st ed., 1788). Though objections may fairly be taken to the fundamental method of this work, there can be no question as to the immense power and originality of its author. His "generalized coordinates," and the equations of motion of a system in terms of these, form one of the most important contributions to the science since the days of Newton. The method of Lagrange, though he was not aware of the fact, is really based upon the consideration of energy; and when, in quite recent times, experiment had shown what are the grand laws of energy, Lagrange's magnificent mathematical methods and results were ready for translation into the new language of science.

3. Hamilton's papers in the *Philosophical Transactions* for 1833 and 1834. Here the principle of varying action, and the characteristic function, were first applied to mechanics;—though they had been given, some years before, to the Royal Irish Academy, in their optical applications. Grand as have been the extensions of these new ideas made by Hamilton himself, and by many others, among whom Jacobi and Liouville may be especially mentioned, they have been mainly in a purely mathematical direction. We wait for what cannot now be long delayed, the coming of the philosopher who is to tell us the true *dynamical* bearings of varying action and of the characteristic function.

4. If to these we add some of the works of Galileo, Huygens, Euler, Maclaurin, and D'Alembert, we have the great landmarks in the history of the subject, as distinguished from its development.

5. The mere enumeration of the more important developments which the subject has received, as distinguished from the absolutely new grand ideas and methods introduced, would require a long article. Brilliant examples of what may be done in this direction are furnished by Stokes's "Report on Recent Researches in Hydrodynamics" and by Cayley's "Reports on Theoretical Dynamics" (printed in the *British Association Reports* for 1846, and for 1857 and 1862). These should be consulted by every student who desires to trace the growth of the subject. They have been succeeded, in the same *Reports* (1880, 1881) by two excellent summaries, by Hicks, of "Recent Progress in Hydrodynamics."

But Laplace's *Mécanique Celeste*, Poisson's *Mécanique*, Poinsot's *Théorie Nouvelle de la Rotation*, &c., more or less parts of the immediate outcome of the period when France intellectually dwarfed the rest of the world, are still of far more than mere historic value.

For the English-reading student of modern times, the work of Thomson and Tait will be found suitable. The authors of this work claim the position of "restorers," not of innovators; and they have (since 1863, when the first short sketch of their work was published) striven with success to re-establish in Britain Newton's grand yet simple foundations of the subject. But these foundations, as stated above, are only temporarily the best. We have not, *as yet*, anything nearly so good.

Other modern works of value are the *Analytic Mechanics* of the late Professor Peirce (Boston, 1855) and Kirchhoff's *Vorlesungen über Mathematische Physik* (Leipsic, 1876). Both are rather of the nature of collections of short treatises on special questions than organized wholes, but both will well repay careful reading. This, in the case of Peirce's work, is rendered extremely puzzling and laborious by the peculiar notations and modes of reference adopted by the author. It is particularly interesting to study the ways in which the fundamental principles are introduced in these works, and to compare them with the corresponding parts of the works of Newton and Lagrange. Lagrange, Peirce, and Kirchhoff construct each a system as free from anything but analysis as possible. In fact Lagrange prefaces his work by the characteristic statement, "On ne trouvera point de Figures dans cet ouvrage. Les méthodes que j'y expose ne demandent ni constructions, ni raisonnemens géométriques ou méchaniques, mais seulement des opérations algébriques, assujetties à une marche réguliere et uniforme. Ceux qui aiment l'Analyse verront avec plaisir la Méchanique en devenir une nouvelle branche." . . . . How far we have considered it expedient to differ from such an authority, a glance at the preceding pages will show.

A part of the detailed work of several of the examples above given in *Dynamics of a Particle* has been taken from the elementary treatise (with that title) of Tait and Steele. The English reader who wishes to pursue elementary Statics may profitably consult the treatise of Minchin. The higher parts are discussed in the work of Somoff, *Theoretische Mechanik* (Leipsic, 1879). An excellent introduction to the use of Generalized Coordinates has been published by Watson and Burbury (1879). On Lagrange's Generalized Equations the student should also read in Maxwell's *Treatise on Electricity and Magnetism*, part iv. chap. v. And Maxwell's brief treatise on *Matter and Motion* should be in the hands of every one commencing the subject.

ANALYSIS OF THE PRECEDING ARTICLE.

NEWTON'S LAWS OF MOTION, *with Comments, assumed as the basis of the article*, §§ 1–13.

KINEMATICS: *Position*, §§ 14–19; *Kinematics of Point*, §§ 20–70; *of Plane Figure in its own Plane*, §§ 71–74; *of Rigid Figure*, §§ 75–83; *of Deformable Figure*, §§ 84–95.

DYNAMICS OF A PARTICLE: *General Considerations*, §§ 96–113; *Further Comments on the First Two Laws of Motion*, §§ 114–119; *Friction*, §§ 120-121; *Statics of a Particle*, §§ 122–128; *Kinetics of a Particle with One Degree of Freedom* (*Meteorite, Hailstone, Pendulum, Cycloidal and Resisted Pendulum*), §§ 129–139; *with Two Degrees of Freedom* (*Planetary Motion, Kepler's Laws and their Consequences, Kinetic Stability*), §§ 140–149; *The Brachistochrone*, §§ 150–152; *Kinetics of a Particle generally* (*Conical Pendulum, Blackburn's and Foucault's Pendulums, Varying Constraint, Disturbed Motion*), §§ 153–163; *Third Law, Kinetics of Two or More Particles* (*Atwood's Machine, Chain-shot, Complex Pendulum*), §§ 164–178; *Kinetics of Free Particles generally, Virial*, § 179; *Impact* (*Continuous Series of Infinitely Small Impacts, Rocket*), §§ 180–190; *Dynamics of a System of Particles generally* (*Equilibrium—Neutral, Stable, and Unstable; Lagrange's General Equation*), §§ 191–199; *Action*, §§ 200–214; *Generalized Coordinates*, §§ 215, 216.

STATICS OF A RIGID SOLID: *Reduction of Forces to Force and Couple, Minding's Theorem, Examples of Statical Problems*, §§ 217–233.

KINETICS OF A RIGID SOLID: *Moment of Inertia, Binet's Theorem, Compound Pendulum, Ballistic Pendulum, Rolling and Sliding of Sphere, Motion about Fixed Point, Poinsot's and Sylvester's Constructions, Quoit, Gyroscopic Pendulum*, §§ 234–257.

STATICS OF A CHAIN: *Common Catenary, Catenary of Uniform Strength, Kinetic Analogy, Chain Stretched on Surface*, §§ 258–264.

KINETICS OF A CHAIN: *Wave Propagation, Musical String, Chain with One End Free, Impulsive Tension, Longitudinal Wave*, §§ 265–270.

DYNAMICS OF ELASTIC SOLID: *Flexure and Torsion of Wire, Bending of Plank, Oscillation of Flat Spring, Distortion of Cylinders and Spheres by Internal and External Hydrostatic Pressure*, §§ 271–284.

GENERAL CONSIDERATIONS ABOUT FORCE AND ENERGY: *Newton's Idea of Force, Origin of the Conception, Stress, Objective Physical Realities, True Nature of Force, Rates in General, Potential Energy in its Nature Kinetic, Maxwell on Inertia, True Laws of Motion*, §§ 285–299.

*References to Authoritative Works*, §§ 301, 302. (P. G. T.)

# APPLIED MECHANICS.

1. **The practical applications of mechanics** may be divided into two classes, according as the assemblages of material objects to which they relate are intended to remain fixed or to move relatively to each other,—the former class being comprehended under the term "Theory of Structures," and the latter under the term "Theory of Machines." As the details of the theory of structures are dealt with in other articles, it will be treated of here to such extent only as may be necessary in order to state certain general principles applicable to all these subjects. The greater part of the article will relate to machines.

## PART I. OUTLINE OF THE THEORY OF STRUCTURES.

2. *Support of Structures.*—Every structure, as a whole, is maintained in equilibrium by the joint action of its own *weight*, of the *external load* or pressure applied to it from without and tending to displace it, and of the *resistance* of the material which supports it. A structure is supported either by resting on the solid crust of the earth, as buildings do, or by floating in a fluid, as ships do in water and balloons in air. The principles of the support of a floating structure form an important part of HYDROMECHANICS (*q.v.*). The principles of the support, as a whole, of a structure resting on the land, are so far identical with those which regulate the equilibrium and stability of the several parts of that structure, and of which a summary will presently be given, that the only principle which seems to require special mention here is one which comprehends in one statement the power both of liquids and of loose earth to support structures, and which was first demonstrated in a paper "On the Stability of Loose Earth," read to the Royal Society on the 19th of June 1856, and published in the *Philosophical Transactions* for that year, viz.:—

Let E represent the weight of the portion of a horizontal stratum of earth which is displaced by the foundation of a structure, S the utmost weight of that structure consistently with the power of the earth to resist displacement, $\phi$ the angle of repose of the earth; then

$$\frac{S}{E} = \left(\frac{1+\sin\phi}{1-\sin\phi}\right)^2$$

To apply this to liquids, $\phi$ must be made $=0$, and then $\frac{S}{E}=1$, as is well known.

3. *Composition of a Structure, and Connexion of its Pieces.*—A structure is composed of *pieces*,—such as the stones of a building in masonry, the beams of a timber frame-work, the bars, plates, and bolts of an iron bridge. Those pieces are connected at their *joints* or surfaces of mutual contact, either by simple pressure and friction (as in masonry with moist mortar or without mortar), by pressure and adhesion (as in masonry with cement or with hardened mortar, and timber with glue), or by the resistance of *fastenings* of different kinds, whether made by means of the form of the joint (as dovetails, notches, mortises, and tenons) or by separate fastening pieces (as trenails, pins, spikes, nails, holdfasts, screws, bolts, rivets, hoops, straps, and sockets).

4. *Stability, Stiffness, and Strength.*—A structure may be damaged or destroyed in three ways,—first, by *displacement* of its pieces from their proper positions relatively to each other or to the earth, secondly, by *disfigurement* of one or more of those pieces, owing to their being unable to preserve their proper shapes under the pressures to which they are subjected, thirdly, by *breaking* of one or more of those pieces. The power of resisting displacement constitutes *stability*; the power of each piece to resist disfigurement is its *stiffness*; and its power to resist breaking, its *strength*.

5. *Conditions of Stability.*—The principles of the stability of a structure can be to a certain extent investigated independently of the stiffness and strength, by assuming, in the first instance, that each piece has strength sufficient to be safe against being broken, and stiffness sufficient to prevent its being disfigured to an extent inconsistent with the purposes of the structure, by the greatest forces which are to be applied to it. The condition that each piece of the structure is to be maintained in equilibrium by having its gross load, consisting of its own weight and of the external pressure applied to it, balanced by the *resistances* or pressures exerted between it and the contiguous pieces, furnishes the means of determining the magnitude, position, and direction of the resistances required at each joint in order to produce equilibrium; and the *conditions of stability* are, first, that the *position*, and, secondly, that the *direction*, of the resistance required at each joint shall, under all the variations to which the load is subject, be such as the joint is capable of exerting,—conditions which are fulfilled by suitably adjusting the figures and positions of the joints, and the *ratios* of the gross loads of the pieces. As for the *magnitude* of the resistance, it is limited by conditions, not of stability, but of strength and stiffness.

6. *Principle of Least Resistance.*—Where more than one system of resistances are alike capable of balancing the same system of loads applied to a given structure, it has been demonstrated by Moseley that the *smallest* of those alternative systems is that which will actually be exerted,—because the resistances to displacement are the effect of a strained state of the pieces, which strained state is the effect of the load, and when the load is applied the strained state and the resistances produced by it increase until the resistances acquire just those magnitudes which are sufficient to balance the load, after which they increase no further.

This principle of least resistance renders determinate many problems in the statics of structures which were formerly considered indeterminate.

7. *Relations between Polygons of Loads and of Resistances.*—In a structure in which each piece is supported at two joints only, the well-known laws of statics show that the directions of the gross load on each piece and of the two resistances by which it is supported must lie in one plane, must either be parallel or meet in one point, and must bear to each other, if not parallel, the proportions of the sides of a triangle respectively parallel to their directions, and, if parallel, such proportions that each of the three forces shall be proportional to the distance between the other two,—all the three distances being measured along one direction.

Considering, in the first place, the case in which the load and the two resistances by which each piece is balanced meet in one point, which may be called the *centre of load*, there will be as many such points of intersection, or centres of load, as there are pieces in the structure; and the directions and positions of the resistances or mutual pressures exerted between the pieces will be represented by the sides of a polygon joining those points, as in fig. 1, where $P_1$, $P_2$, $P_3$, $P_4$ represent the centres of load in a structure of four pieces, and the sides of the *polygon of resistances* $P_1P_2P_3P_4$ represent respectively the directions and positions of the resistances exerted at the joints. Further, at any one of the centres of load let PL represent the magnitude and direction of the gross load, and Pa, Pb the two resistances by which the piece to which that load is applied is supported; then will those three lines be respectively the diagonal and sides of a parallelogram; or, what is the same thing, they will be equal to the three sides of a triangle; and they must be in the same plane, although the sides of the polygon of resistances may be in different planes.

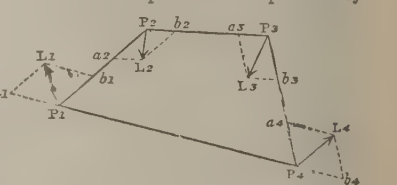

Fig. 1.

According to a well-known principle of statics, because the loads or external pressures $P_1L_1$, &c., balance each other, they must be proportional to the sides of a closed polygon drawn respectively parallel to their directions. In fig. 2 construct such a *polygon of loads* by drawing the lines $L_1$, &c., parallel and proportional to, and joined end to end in the order of, the gross loads on the pieces of the structure. Then from the proportionality and parallelism of the load and the two resistances applied to each piece of the structure to the three sides of a triangle, there results the following theorem [originally due to Rankine]:—

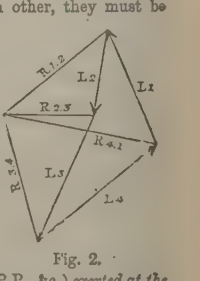

Fig. 2.

*If from the angles of the polygon of loads there be drawn lines* ($R_1$, $R_2$, &c.), *each of which is parallel to the resistance* (as $P_1P_2$, &c.) *exerted at the joint between the pieces to which the two loads represented by the contiguous sides of the polygon of loads* (such as $L_1$, $L_2$, &c.) *are applied; then will all those lines meet in one point* (O), *and their lengths, measured from that point to the angles of the polygon, will represent the magnitudes of the resistances to which they are respectively parallel.*

When the load on one of the pieces is parallel to the resistances which balance it, the polygon of resistances ceases to be closed, two of the sides becoming parallel to each other and to the load in question, and extending indefinitely. In the polygon of loads the direction of a load sustained by parallel resistances traverses the point O.

8. *How the Earth's Resistance is to be treated.*—When the pressure exerted by a structure on the earth (to which the earth's resistance is equal and opposite) consists either of one pressure, which is necessarily the resultant of the weight of the structure and of all the other forces applied to it, or of two or more parallel vertical forces, whose amount can be determined at the outset of the

investigation, the resistance of the earth can be treated as one or more *upward loads* applied to the structure. But in other cases the earth is to be treated as *one of the pieces of the structure*, loaded with a force equal and opposite in direction and position to the resultant of the weight of the structure and of the other pressures applied to it.

9. *Partial Polygons of Resistance.*—In a structure in which there are pieces supported at more than two joints, let a polygon be constructed of lines connecting the centres of load of any continuous series of pieces. This may be called a *partial polygon of resistances*. In considering its properties, the *load* at each centre of load is to be held to *include* the resistances of those joints which are *not* comprehended in the partial polygon of resistances, to which the theorem of section 7 will then apply in every respect. By constructing several partial polygons, and computing the relations between the loads and resistances which are determined by the application of that theorem to each of them, with the aid, if necessary, of Moseley's principle of the least resistance, the whole of the relations amongst the loads and resistances may be found.

10. *Line of Pressures—Centres and Line of Resistance.*—The *line of pressures* is a line to which the directions of all the resistances in one polygon are tangents. The *centre of resistance* at any joint is the point where the line representing the total resistance exerted at that joint intersects the joint. The *line of resistance* is a line traversing all the centres of resistance of a series of joints,—its form, in the positions intermediate between the actual joints of the structure, being determined by supposing the pieces and their loads to be subdivided by the introduction of intermediate joints *ad infinitum*, and finding the continuous line, curved or straight, in which the intermediate centres of resistance are all situated, however great their number. The difference between the line of resistance and the line of pressures was first pointed out by Moseley.

11. *Stability of Position, and Stability of Friction.*—The resistances at the several joints having been determined by the principles set forth in sections 6, 7, 8, 9, and 10, not only under the ordinary load of the structure, but under all the variations to which the load is subject as to amount and distribution, the joints are now to be placed and shaped so that the pieces shall not suffer relative displacement under any of those loads. The relative displacement of the two pieces which abut against each other at a joint may take place either by turning or by sliding. Safety against displacement by turning is called *stability of position*; safety against displacement by sliding, *stability of friction*.

12. *Condition of Stability of Position.*—If the materials of a structure were infinitely stiff and strong, stability of position at any joint would be insured simply by making the centre of resistance fall within the joint under all possible variations of load. In order to allow for the finite stiffness and strength of materials, the least distance of the centre of resistance inward from the nearest edge of the joint is made to bear a definite proportion to the depth of the joint measured in the same direction, which proportion is fixed, sometimes empirically, sometimes by theoretical deduction from the laws of the strength of materials. That least distance is called by Moseley the *modulus of stability*. The following are some of the ratios of the modulus of stability to the depth of the joint which occur in practice :—

| | |
|---|---|
| Retaining walls, as designed by British engineers | 1 : 8 |
| Retaining walls, as designed by French engineers | 1 : 5 |
| Rectangular piers of bridges and other buildings, and arch-stones | 1 : 3 |
| Rectangular foundations, firm ground | 1 : 3 |
| Rectangular foundations, very soft ground | 1 : 2 |
| Rectangular foundations, intermediate kinds of ground | 1 : 3 to 1 : 2 |
| Thin, hollow towers (such as furnace chimneys exposed to high winds), square | 1 : 6 |
| Thin, hollow towers, circular | 1 : 4 |
| Frames of timber or metal, under their ordinary or average distribution of load | 1 : 3 |
| Frames of timber or metal, under the greatest irregularities of load | 1 : 3 |

In the case of the towers, the *depth of the joint* is to be understood to mean the *diameter of the tower*.

13. *Condition of Stability of Friction.*—If the resistance to be exerted at a joint is always perpendicular to the surfaces which abut at and form that joint, there is no tendency of the pieces to be displaced by sliding. If the resistance be oblique, let JK (fig. 3) be the joint, C its centre of resistance, CR a line representing the resistance, CN a perpendicular to the joint at the centre of resistance. The angle NCR is the *obliquity* of the resistance. From R draw RP parallel and RQ perpendicular to the joint; then, by the principles of statics, the component of the resistance *normal* to the joint is—

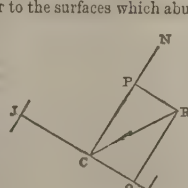

Fig. 3.

$$CP = CR \cdot \cos \angle PRC;$$

and the component *tangential* to the joint is—

$$CQ = CR \cdot \sin \angle PCR = CP \cdot \tan \angle PCR.$$

If the joint be provided either with projections and recesses, such as mortises and tenons, or with fastenings, such as pins or bolts, so as to resist displacement by sliding, the question of the utmost amount of the tangential resistance CQ which it is capable of exerting depends on the *strength* of such projections, recesses, or fastenings, and belongs to the subject of strength, and not to that of stability. In other cases the safety of the joint against displacement by sliding depends on its power of exerting friction, and that power depends on the law, known by experiment, that the friction between two surfaces bears a constant ratio, depending on the nature of the surfaces, to the force by which they are pressed together. In order that the surfaces which abut at the joint JK may be pressed together, the resistance required by the conditions of equilibrium, CR, must be a *thrust* and not a *pull*; and in that case the force by which the surfaces are pressed together is equal and opposite to the normal component CP of the resistance. The condition of stability of friction is that the tangential component CQ of the resistance required shall not exceed the friction due to the normal component; that is, that

$$CQ \not> f \cdot CP,$$

where $f$ denotes the *coefficient of friction* for the surfaces in question. The angle whose tangent is the coefficient of friction is called *the angle of repose*, and is expressed symbolically by—

$$\phi = \tan^{-1} f.$$

$$\text{Now } CQ = CP \cdot \tan \angle PCR;$$

consequently the condition of stability of friction is fulfilled if

$$\angle PCR \not> \phi;$$

that is to say, if *the obliquity of the resistance required at the joint does not exceed the angle of repose*; and this condition ought to be fulfilled under all possible variations of the load.

It is chiefly in masonry and earthwork that stability of friction is relied on.

14. *Stability of Friction in Earth.*—The grains of a mass of loose earth are to be regarded as so many separate pieces abutting against each other at joints in all possible positions, and depending for their stability on friction. To determine whether a mass of earth is stable at a given point, conceive that point to be traversed by planes in all possible positions, and determine which position gives the greatest obliquity to the total pressure exerted between the portions of the mass which abut against each other at the plane. The condition of stability is that this obliquity shall not exceed the angle of repose of the earth. The consequences of this principle are developed in a paper "On the Stability of Loose Earth," already cited in sect. 2.

15. *Parallel Projections of Figures.*—If any figure be referred to a system of coordinates, rectangular or oblique, and if a second figure be constructed by means of a second system of coordinates, rectangular or oblique, and either agreeing with or differing from the first system in rectangularity or obliquity, but so related to the coordinates of the first figure that for each point in the first figure there shall be a corresponding point in the second figure, the lengths of whose coordinates shall bear respectively to the three corresponding coordinates of the corresponding point in the first figure three ratios which are the same for every pair of corresponding points in the two figures, these corresponding figures are called *parallel projections* of each other. The properties of parallel projections of most importance to the subject of the present article are the following :—

(1) A parallel projection of a straight line is a straight line.

(2) A parallel projection of a plane is a plane.

(3) A parallel projection of a straight line or a plane surface divided in a given ratio is a straight line or a plane surface divided in the same ratio.

(4) A parallel projection of a pair of equal and parallel straight lines, or plain surfaces, is a pair of equal and parallel straight lines, or plane surfaces; whence it follows

(5) That a parallel projection of a parallelogram is a parallelogram, and

(6) That a parallel projection of a parallelepiped is a parallelepiped.

(7) A parallel projection of a pair of solids having a given ratio is a pair of solids having the same ratio.

Though not essential for the purposes of the present article, the following consequence will serve to illustrate the principle of parallel projections :—

(8) A parallel projection of a curve, or of a surface of a given algebraical order, is a curve or a surface of the same order.

For example, all ellipsoids referred to coordinates parallel to any three conjugate diameters are parallel projections of each other and of a sphere referred to rectangular coordinates.

16. *Parallel Projections of Systems of Forces.*—If a balanced system of forces be represented by a system of lines, then will every parallel projection of that system of lines represent a balanced system of forces.

For the condition of equilibrium of forces not parallel is that they shall be represented in direction and magnitude by the sides and diagonals of certain parallelograms, and of parallel forces that they shall divide certain straight lines in certain ratios; and the parallel projection of a parallelogram is a parallelogram, and that of a straight line divided in a given ratio is a straight line divided in the same ratio.

The resultant of a parallel projection of any system of forces is the projection of their resultant; and the centre of gravity of a parallel projection of a solid is the projection of the centre of gravity of the first solid.

17. *Principle of the Transformation of Structures.*—Here we have the following theorem:—If a structure of a given figure have stability of position under a system of forces represented by a given system of lines, then will any structure whose figure is a parallel projection of that of the first structure have stability of position under a system of forces represented by the corresponding projection of the first system of lines.

For in the second structure the weights, external pressures, and resistances will balance each other as in the first structure; the weights of the pieces and all other parallel systems of forces will have the same ratios as in the first structure; and the several centres of resistance will divide the depths of the joints in the same proportions as in the first structure.

If the first structure have stability of friction, the second structure will have stability of friction also, so long as the effect of the projection is not to increase the obliquity of the resistance at any joint beyond the angle of repose.

The lines representing the forces in the second figure show their *relative* directions and magnitudes. To find their *absolute* directions and magnitudes, a vertical line is to be drawn in the first figure, of such a length as to represent the weight of a particular portion of the structure. Then will the projection of that line in the projected figure indicate the vertical direction, and represent the weight of the part of the second structure corresponding to the beforementioned portion of the first structure.

The foregoing "principle of the transformation of structures" was first announced, though in a somewhat less comprehensive form, to the Royal Society on the 6th of March 1856. It is useful in practice, by enabling the engineer easily to deduce the conditions of equilibrium and stability of structures of complex and unsymmetrical figures from those of structures of simple and symmetrical figures. By its aid, for example, the whole of the properties of elliptical arches, whether square or skew, whether level or sloping in their span, are at once deduced by projection from those of symmetrical circular arches, and the properties of ellipsoidal and elliptic-conoidal domes from those of hemispherical and circular-conoidal domes; and the figures of arches fitted to resist the thrust of earth, which is less horizontally than vertically in a certain given ratio, can be deduced by a projection from those of arches fitted to resist the thrust of a liquid, which is of equal intensity, horizontally and vertically.

18. *Conditions of Stiffness and Strength.*—After the arrangement of the pieces of a structure and the size and figure of their joints or surfaces of contact have been determined so as to fulfil the conditions of *stability*,—conditions which depend mainly on the position and direction of the *resultant* or *total* load on each piece, and the *relative* magnitude of the loads on the different pieces,—the dimensions of each piece singly have to be adjusted so as to fulfil the conditions of *stiffness* and *strength*,—conditions which depend not only on the *absolute* magnitude of the load on each piece, and of the resistances by which it is balanced, but also on the *mode of distribution* of the load over the piece, and of the resistances over the joints.

The effect of the pressures applied to a piece, consisting of the load and the supporting resistances, is to force the piece into a state of *strain* or disfigurement, which increases until the elasticity, or resistance to strain, of the material causes it to exert a *stress*, or effort to recover its figure, equal and opposite to the system of applied pressures. The condition of *stiffness* is that the strain or disfigurement shall not be greater than is consistent with the purposes of the structure; and the condition of *strength* is that the stress shall be within the limits of that which the material can bear with safety against breaking. The ratio in which the utmost stress before breaking exceeds the safe working stress is called the *factor of safety*, and is determined empirically. It varies from three to twelve for various materials and structures.

The STRENGTH OF MATERIALS forms the subject of a special article, to which the reader is referred.

## PART II. THEORY OF MACHINES.

19. *Parts of a Machine—Frame and Mechanism.*—The parts of a machine may be distinguished into two principal divisions,—the *frame*, or fixed parts, and the *mechanism*, or moving parts. The frame is a structure which supports the pieces of the mechanism, and to a certain extent determines the nature of their motions. The form and arrangement of the pieces of the frame depend upon the arrangement and the motions of the mechanism; the dimensions of the pieces of the frame required in order to give it stability and strength are determined from the pressures applied to it by means of the mechanism. It appears therefore that in general the mechanism is to be designed first and the frame afterwards, and that the designing of the frame is regulated by the principles of the stability of structures and of the strength and stiffness of materials,—care being taken to adapt the frame to the most severe load which can be thrown upon it at any period of the action of the mechanism.

Each independent piece of the mechanism also is a structure, and its dimensions are to be adapted, according to the principles of the strength and stiffness of materials, to the most severe load to which it can be subjected during the action of the machine.

20. *Definition and Division of the Theory of Machines.*—From what has been said in the last section it appears that the department of the art of designing machines which has reference to the stability of the frame and to the stiffness and strength of the frame and mechanism is a branch of the art of construction. It is therefore to be separated from the *theory of machines*, properly speaking, which has reference to the action of machines considered as moving. In the action of a machine the following three things take place:—

*First*, Some natural source of energy communicates motion and force to a piece or pieces of the mechanism, called the *receiver of power* or *prime mover*.

*Secondly*, The motion and force are transmitted from the prime mover through the *train of mechanism* to the *working piece* or *pieces*, and during that transmission the motion and force are modified in amount and direction, so as to be rendered suitable for the purpose to which they are to be applied.

*Thirdly*, The working piece or pieces by their motion, or by their motion and force combined, produce some useful effect.

Such are the phenomena of the action of a machine, arranged in the order of *causation*. But in studying or treating of the theory of machines, the order of *simplicity* is the best; and in this order the first branch of the subject is the modification of motion and force by the train of mechanism; the next is the effect or purpose of the machine; and the last, or most complex, is the action of the prime mover.

The modification of motion and the modification of force take place together, and are connected by certain laws; but in the study of the theory of machines, as well as in that of pure mechanics, much advantage has been gained in point of clearness and simplicity by first considering alone the principles of the modification of motion, which are founded upon what is now known as Kinematics, and afterwards considering the principles of the combined modification of motion and force, which are founded both on geometry and on the laws of dynamics. The separation of kinematics from dynamics is due mainly to Monge, Ampère, and Willis.

The theory of machines in the present article will be considered under the following four heads:—

I. PURE MECHANISM, or APPLIED KINEMATICS; being the theory of machines considered simply as modifying motion.
II. APPLIED DYNAMICS; being the theory of machines considered as modifying both motion and force.
III. PURPOSES AND EFFECTS OF MACHINES.
IV. APPLIED ENERGETICS; being the theory of prime movers and sources of power.

### CHAP. I. ON PURE MECHANISM.

21. *Division of the Subject.*—Proceeding in the order of simplicity, the subject of Pure Mechanism, or Applied Kinematics may be thus divided:—

*Division* 1.—Motion of a point.
*Division* 2.—Motion of the surface of a fluid.
*Division* 3.—Motion of a rigid solid.
*Division* 4.—Motions of a pair of connected pieces, or of an "elementary combination" in mechanism.
*Division* 5.—Motions of trains of pieces of mechanism.
*Division* 6.—Motions of sets of more than two connected pieces, or of "aggregate combinations."

A point is the boundary of a line, which is the boundary of a surface, which is the boundary of a volume. Points, lines, and surfaces have no independent existence, and consequently those divisions of this chapter which relate to their motions are only preliminary to the subsequent divisions, which relate to the motions of bodies.

#### *Division* 1. *Motion of a Point.*

22. *Path and Direction.*—See above, p. 679, § 21.
23. *Uniform Velocity.*—See p. 680, § 25.
24. *Varied Velocity.*—See p. 680, § 25.
25. *Direct Deviation, or Acceleration and Retardation.*—See pp. 680, 681, §§ 27–29.

26. *Lateral Deviation or Deflexion—Angular Velocity of Deviation—Revolution.*—See pp. 681, 682, §§ 31–38.

27. *Comparative Motion.*—The comparative motion of two points is the relation which exists between their motions, without having regard to their absolute amounts. It consists of two elements,—the *velocity ratio*, which is the ratio of any two magnitudes bearing to each other the proportions of the respective velocities of the two points at a given instant, and the *directional relation*, which is the relation borne to each other by the respective directions of the motions of the two points at the same given instant.

It is obvious that the motions of a pair of points may be varied in any manner, whether by direct or by lateral deviation, and yet that their *comparative motion* may remain constant, in consequence of the deviations taking place in the same proportions, in the same directions, and at the same instants for both points.

Willis has the merit of having been the first to simplify considerably the theory of pure mechanism, by pointing out that that branch of mechanics relates wholly to comparative motions.

The comparative motion of two points at a given instant is capable of being completely expressed by one of Sir William Hamilton's Quaternions,—the "tensor" expressing the velocity ratio, and the "versor" the directional relation.

28. *Resolution and Composition of Motion.*—See p. 681, §§ 30, 31.

29. *Rectangular Projection, Resolution, and Composition.*—See p. 681, § 31.

30. *Resolution and Composition of Deviations.*—See p. 681, § 31.

*Division* 2. *Motion of the Surface of a Fluid Mass.*

31. *General Principle.*—A mass of fluid is used in mechanism to transmit motion and force between two or more movable portions (called *pistons* or *plungers*) of the solid envelope or vessel in which the fluid is contained; and, when such transmission is the sole action, or the only appreciable action of the fluid mass, its volume is either absolutely constant, by reason of its temperature and pressure being maintained constant, or not sensibly varied.

Let $a$ represent the area of the section of a piston made by a plane perpendicular to its direction of motion, and $v$ its velocity, which is to be considered as positive when outward, and negative when inward. Then the variation of the cubic contents of the vessel in a unit of time by reason of the motion of one piston is $va$. The condition that the volume of the fluid mass shall remain unchanged requires that there shall be more than one piston, and that the velocities and areas of the pistons shall be connected by the equation—

$$\Sigma . va = 0 \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (1).$$

32. *Comparative Motion of two Pistons.*—If there be but two pistons, whose areas are $a_1$ and $a_2$, and their velocities $v_1$ and $v_2$, their comparative motion is expressed by the equation—

$$\frac{v_2}{v_1} = -\frac{a_1}{a_2} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (2);$$

that is to say, their velocities are opposite as to inwardness and outwardness, and inversely proportional to their areas.

33. *Applications—Hydraulic Press—Pneumatic Power-Transmitter.*—In the hydraulic press the vessel consists of two cylinders, viz., the pump-barrel and the press-barrel, each having its piston, and of a passage connecting them having a valve opening towards the press-barrel. The action of the enclosed water in transmitting motion takes place during the inward stroke of the pump-plunger, when the above-mentioned valve is open; and at that time the press-plunger moves outwards with a velocity which is less than the inward velocity of the pump-plunger, in the same ratio that the area of the pump-plunger is less than the area of the press-plunger. (See HYDROMECHANICS.)

In the pneumatic power-transmitter the motion of one piston is transmitted to another at a distance by means of a mass of air contained in two cylinders and an intervening tube. When the pressure and temperature of the air can be maintained constant, this machine fulfils equation 2, like the hydraulic press. The amount and effect of the variations of pressure and temperature undergone by the air depend on the principles of the mechanical action of heat, or THERMODYNAMICS (*q.v.*), and are foreign to the subject of pure mechanism.

*Division* 3. *Motion of a Rigid Solid.*

34. *Motions Classed.*—In problems of mechanism, each solid piece of the machine is supposed to be so stiff and strong as not to undergo any sensible change of figure or dimensions by the forces applied to it,—a supposition which is realized in practice if the machine is skilfully designed.

This being the case, the various possible motions of a rigid solid body may all be classed under the following heads:—(1) *Shifting or Translation*; (2) *Turning or Rotation*; (3) *Motions compounded of Shifting and Turning.*

The most common forms for the paths of the points of a piece of mechanism, whose motion is simple shifting, are the straight line and the circle.

Shifting in a straight line is regulated either by straight fixed guides, in contact with which the moving piece slides, or by combinations of link-work, called *parallel motions*, which will be described in the sequel. Shifting in a straight line is usually *reciprocating*; that is to say, the piece, after shifting through a certain distance, returns to its original position by reversing its motion.

Circular shifting is regulated by attaching two or more points of the shifting piece to ends of equal and parallel rotating cranks, or by combinations of wheel-work to be afterwards described. As an example of circular shifting may be cited the motion of the coupling rod, by which the parallel and equal cranks upon two or more axles of a locomotive engine are connected and made to rotate simultaneously. The coupling rod remains always parallel to itself, and all its points describe equal and similar circles relatively to the frame of the engine, and move in parallel directions with equal velocities at the same instant.

35. *Rotation about a Fixed Axis—Lever, Wheel, and Axle.*—The fixed axis of a turning body is a line fixed relatively to the body and relatively to the fixed space in which the body turns. In mechanism it is usually the central line either of a rotating shaft or axle having journals, gudgeons, or pivots turning in fixed bearings, or of a fixed spindle or dead centre round which a rotating bush turns; but it may sometimes be entirely beyond the limits of the turning body. For example, if a sliding piece moves in circular fixed guides, that piece rotates about an ideal fixed axis traversing the centre of those guides.

Let the angular velocity of the rotation be denoted by $\alpha = \frac{d\theta}{dt}$, then the linear velocity of any point A at the distance $r$ from the axis is $\alpha r$; and the path of that point is a circle of the radius $r$ described about the axis.

This is the principle of the modification of motion by the lever, which consists of a rigid body turning about a fixed axis called a fulcrum, and having two points at the same or different distances from that axis, and in the same or different directions, one of which receives motion and the other transmits motion, modified in direction and velocity according to the above law.

In the wheel and axle, motion is received and transmitted by two cylindrical surfaces of different radii described about their common fixed axis of turning, their velocity-ratio being that of their radii.

36. *Velocity Ratio of Components of Motion.*—As the distance between any two points in a rigid body is invariable, the projections of their velocities upon the line joining them must be equal. Hence it follows that, if A in fig. 4 be a point in a rigid body CD, rotating round the fixed axis F, the component of the velocity of A in any direction AP parallel to the plane of rotation is equal to the total velocity of the point $m$, found by letting fall $Fm$ perpendicular to AP; that is to say, is equal to

$$\alpha . Fm.$$

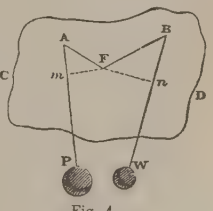

Fig. 4.

Hence also the ratio of the components of the velocities of two points A and B in the directions AP and BW respectively, both in the plane of rotation, is equal to the ratio of the perpendiculars $Fm$ and $Fn$.

37. *Instantaneous Axis of a Cylinder rolling on a Cylinder.*—Let a cylinder *bbb*, whose axis of figure is B and angular velocity $\gamma$, roll on a fixed cylinder *aaa*, whose axis of figure is A, either outside (as in fig. 5), when the rolling will be towards the same hand as the

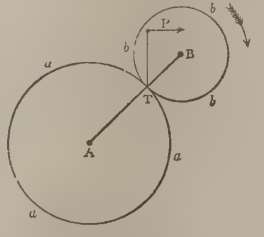

Fig. 5.

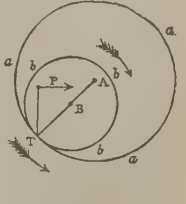

Fig. 6.

rotation, or inside (as in fig. 6), when the rolling will be towards the opposite hand; and at a given instant let T be the line of contact of the two cylindrical surfaces, which is at their common intersection with the plane AB traversing the two axes of figure.

The line T on the surface *bbb* has for the instant no velocity in

a direction perpendicular to AB; because for the instant it touches, without sliding, the line T on the fixed surface *aaa*.

The line T on the surface *bbb* has also for the instant no velocity in the plane AB; for it has just ceased to move towards the fixed surface *aaa*, and is just about to begin to move away from that surface.

The line of contact T, therefore, on the surface of the cylinder *bbb*, is *for the instant* at rest, and is the "instantaneous axis" about which the cylinder *bbb* turns, together with any body rigidly attached to that cylinder.

To find, then, the direction and velocity at the given instant of any point P, either in or rigidly attached to the rolling cylinder T, draw the plane PT; the direction of motion of P will be perpendicular to that plane, and towards the right or left hand according to the direction of the rotation of *bbb* and the velocity of P will be

$$v_P = \gamma \,.\, PT \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (3),$$

PT denoting the perpendicular distance of P from T. The path of P is a curve of the kind called *epitrochoids*. If P is in the circumference of *bbb*, that path becomes an *epicycloid*.

The velocity of any point in the axis of figure B is

$$v_B = \gamma \,.\, TB \quad . \quad . \quad . \quad . \quad . \quad . \quad 4);$$

and the path of such a point is a circle described about A with the radius AB, being for outside rolling the sum, and for inside rolling the difference, of the radii of the cylinders.

Let $\alpha$ denote the angular velocity with which the *plane of axes* AB rotates about the fixed axis A. Then it is evident that

$$v_B = \alpha \,.\, AB \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (5),$$

and consequently that

$$\alpha = \gamma \,.\, \frac{TB}{AB} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (6).$$

For internal rolling, as in fig. 6, AB is to be treated as negative, which will give a negative value to $\alpha$, indicating that in this case the rotation of AB round A is contrary to that of the cylinder *bbb*.

The angular velocity of the rolling cylinder, *relatively to the plane of axes* AB, is obviously given by the equation—

$$\left.\begin{aligned} &\beta = \gamma - \alpha\,; \\ \text{whence } &\beta = \gamma \cdot \frac{TA}{AB} \end{aligned}\right\} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (7);$$

care being taken to attend to the sign of $\alpha$, so that when that is negative the arithmetical values of $\gamma$ and $\alpha$ are to be added in order to give that of $\beta$.

The whole of the foregoing reasonings are applicable, not merely when *aaa* and *bbb* are actual cylinders, but also when they are the osculating cylinders of a pair of cylindroidal surfaces of varying curvature, A and B being the axes of curvature of the parts of those surfaces which are in contact for the instant under consideration.

38. *Composition and Resolution of Rotations about Parallel Axes.*—See above, p. 691, § 73.

39. *Instantaneous Axis of a Cone rolling on a Cone.*—Let O*aa* (fig. 7) be a fixed cone, OA its axis, O*bb* a cone rolling on it, OB the axis of the rolling cone, OT the line of contact of the two cones at the instant under consideration. By reasoning similar to that of sect. 37, it appears that OT is the instantaneous axis of rotation of the rolling cone.

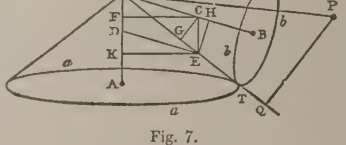

Fig. 7.

Let $\gamma$ denote the total angular velocity of the rotation of the cone B about the instantaneous axis, $\beta$ its angular velocity about the axis OB *relatively* to the plane AOB, and $\alpha$ the angular velocity with which the plane AOB turns round the axis OA. It is required to find the ratios of those angular velocities.

*Solution.*—In OT take any point E, from which draw EC parallel to OA, and ED parallel to OB, so as to construct the parallelogram OCED. Then

$$\left.\begin{aligned} &OD : OC : OE \\ &:: \alpha : \beta : \gamma \end{aligned}\right\} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (8).$$

Or because of the proportionality of the sides of triangles to the sines of the opposite angles,

$$\left.\begin{aligned} &\sin\angle TOB : \sin\angle TOA : \sin\angle AOB \\ &:: \quad \alpha \quad : \quad \beta \quad : \end{aligned}\right\} \quad . \quad . \quad . \quad (8, A);$$

that is to say, the angular velocity about each axis is proportional to the sine of the angle between the other two.

*Demonstration.*—From C draw CF perpendicular to OA, and CG perpendicular to OE.

$$\text{Then } CF = 2 \times \frac{\text{area ECO}}{CE},$$

$$\text{and } CG = 2 \times \frac{\text{area ECO}}{OE};$$

$$\therefore CG : CF :: CE = OD : OE.$$

Let $v_C$ denote the linear velocity of the point C. Then

$$v_C = \alpha \,.\, CF = \gamma \,.\, CG$$

$$\therefore \gamma : \alpha :: CF : CG :: OE : OD,$$

which is one part of the solution above stated. From E draw EH perpendicular to OB, and EK to OA. Then it can be shown as before that

$$EK : EH :: OC : OD.$$

Let $v_E$ be the linear velocity of the point E *fixed in the plane of axes* AOB. Then

$$v_E = \alpha \,.\, EK.$$

Now, as the line of contact OT is for the instant at rest on the rolling cone as well as on the fixed cone, the linear velocity of the point E fixed to the plane AOB relatively to the rolling cone is the same with its velocity relatively to the fixed cone. That is to say,

$$\beta \,.\, EH = v_E = \alpha \,.\, EK;$$

$$\text{therefore} \qquad \alpha : \beta :: EH : EK :: OD : OC,$$

which is the remainder of the solution.

The path of a point P in or attached to the rolling cone is a spherical epitrochoid traced on the surface of a sphere of the radius OP. From P draw PQ perpendicular to the instantaneous axis. Then the motion of P is perpendicular to the plane OPQ, and its velocity is

$$v_P = \gamma \,.\, PQ. \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (9).$$

The whole of the foregoing reasonings are applicable, not merely when A and B are actual regular cones, but also when they are the osculating regular cones of a pair of irregular conical surfaces, having a common apex at O.

40. *Composition of Rotations about Two Axes meeting in a Point.*—See p. 691, § 76.

41. *Screw-like or Helical Motion.*—Since (see p. 690, §§ 71, 72) any displacement in a plane can be represented in general by a rotation, it follows that the only combination of translation and rotation, in which a complex movement which is not a mere rotation is produced, occurs when there is a translation *perpendicular to the plane and parallel to the axis* of rotation.

Such a complex motion is called *screw-like* or *helical* motion; for each point in the body describes a *helix* or *screw* round the axis of rotation, fixed or instantaneous as the case may be. To cause a body to move in this manner it is usually made of a helical or screw-like figure, and moves in a guide of a corresponding figure. Helical motion and screws adapted to it are said to be right- or left-handed according to the appearance presented by the rotation to an observer looking towards the direction of the translation. Thus the screw G in fig. 8 is right-handed.

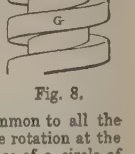

Fig. 8.

The translation of a body in helical motion is called its *advance*. Let $v_x$ denote the velocity of advance at a given instant, which of course is common to all the particles of the body; $\alpha$ the angular velocity of the rotation at the same instant; $2\pi = 6{\cdot}2832$ nearly, the circumference of a circle of the radius unity. Then

$$T = \frac{2\pi}{\alpha} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (10)$$

is the time of one turn at the rate $\alpha$; and

$$p = v_x T = \frac{2\pi v_x}{\alpha} \quad . \quad . \quad . \quad . \quad . \quad . \quad (11)$$

is the *pitch* or *advance per turn*,—a length which expresses the *comparative motion* of the translation and the rotation.

The pitch of a screw is the distance, measured parallel to its axis, between two successive turns of the same *thread* or helical projection.

Let $r$ denote the perpendicular distance of a point in a body moving helically from the axis. Then

$$v_r = \alpha r \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (12)$$

is the component of the velocity of that point in a plane perpendicular to the axis, and its total velocity is

$$v = \sqrt{\{v_x^2 + v_r^2\}} \quad . \quad . \quad . \quad . \quad . \quad . \quad (13).$$

The ratio of the two components of that velocity is

$$\frac{v_x}{v_r} = \frac{p}{2\pi r} = \tan\theta \quad . \quad . \quad . \quad . \quad . \quad . \quad (14);$$

where $\theta$ denotes the angle made by the helical path of the point with a plane perpendicular to the axis.

42. *To find the Motion of a Rigid Body from the Motions of Three Points in it.*—See p. 690, § 71, and p. 692, § 78.

*Division 4. Elementary Combinations in Mechanism.*

43. *Definitions.*—An *elementary combination* in mechanism consists of two pieces whose kinds of motion are determined by their connexion with the frame, and their comparative motion by their connexion with each other,—that connexion being effected either by direct contact of the pieces, or by a connecting piece, which is not connected with the frame, and whose motion depends entirely on the motions of the pieces which it connects.

The piece whose motion is the cause is called the *driver*; the piece whose motion is the effect, the *follower*.

The connexion of each of those two pieces with the frame is in general such as to determine the path of every point in it. In the investigation, therefore, of the comparative motion of the driver and follower, in an elementary combination, it is unnecessary to consider relations of angular direction, which are already fixed by the connexion of each piece with the frame; so that the inquiry is confined to the determination of the velocity ratio, and of the directional relation, so far only as it expresses the connexion between *forward* and *backward* movements of the driver and follower. When a continuous motion of the driver produces a continuous motion of the follower, forward or backward, and a reciprocating motion a motion reciprocating at the same instant, the directional relation is said to be *constant*. When a continuous motion produces a reciprocating motion, or *vice versa*, or when a reciprocating motion produces a motion not reciprocating at the same instant, the directional relation is said to be *variable*.

The *line of action* or *of connexion* of the driver and follower is a line traversing a pair of points in the driver and follower respectively, which are so connected that the component of their velocity relatively to each other, resolved along the line of connexion, is null. There may be several or an indefinite number of lines of connexion, or there may be but one; and a line of connexion may connect either the same pair of points or a succession of different pairs.

44. *General Principle.*—From the definition of a line of connexion it follows that *the components of the velocities of a pair of connected points along their line of connexion are equal.* And from this, and from the property of a rigid body, already stated in sect. 36, it follows, that *the components along a line of connexion of all the points traversed by that line, whether in the driver or in the follower, are equal*; and consequently, *that the velocities of any pair of points traversed by a line of connexion are to each other inversely as the cosines, or directly as the secants, of the angles made by the paths of those points with the line of connexion.*

The general principle stated above in different forms serves to solve every problem in which—the mode of connexion of a pair of pieces being given—it is required to find their comparative motion at a given instant, or *vice versa*.

45. *Application to a Pair of Shifting Pieces.*—In fig. 9, let $P_1P_2$ be the line of connexion of a pair of pieces, each of which has a motion of translation or shifting. Through any point T in that line draw $TV_1$, $TV_2$, respectively parallel to the simultaneous direction of motion of the pieces; through any other point A in the line of connexion draw a plane perpendicular to that line, cutting $TV_1$, $TV_2$ in $V_1$, $V_2$; then, velocity of piece 1 : velocity of piece 2 :: $TV_1$ : $TV_2$. Also TA represents the equal components of the velocities of the pieces parallel to their line of connexion, and the line $V_1V_2$ represents their velocity relatively to each other.

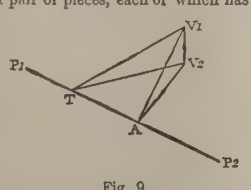

Fig. 9.

46. *Application to a Pair of Turning Pieces.*—Let $\alpha_1$, $\alpha_2$ be the angular velocities of a pair of turning pieces; $\theta_1$, $\theta_2$ the angles which their line of connexion makes with their respective planes of rotation; $r_1$, $r_2$ the common perpendiculars let fall from the line of connexion upon the respective axes of rotation of the pieces. Then the equal components, along the line of connexion, of the velocities of the points where those perpendiculars meet that line are—

$$\alpha_1 r_1 \cos\theta_1 = \alpha_2 r_2 \cos\theta_2 ;$$

consequently, the comparative motion of the pieces is given by the equation

$$\frac{\alpha_2}{\alpha_1} = \frac{r_1 \cos\theta_1}{r_2 \cos\theta_2} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (15).$$

47. *Application to a Shifting Piece and a Turning Piece.*—Let a shifting piece be connected with a turning piece, and at a given instant let $\alpha_1$ be the angular velocity of the turning piece, $r_1$ the common perpendicular of its axis of rotation and the line of connexion, $\theta_1$ the angle made by the line of connexion with the plane of rotation, $\theta_2$ the angle made by the line of connexion with the direction of motion of the shifting piece, $v_2$ the linear velocity of that piece. Then

$$\alpha_1 r_1 \cos\theta_1 = v_2 \cos\theta_2 \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (16)$$

which equation expresses the comparative motion of the two pieces.

48. *Classification of Elementary Combinations in Mechanism.*—The first systematic classification of elementary combinations in mechanism was that founded by Monge, and fully developed by Lanz and Bétancourt, which has been generally received, and has been adopted in most treatises on applied mechanics. But that classification is founded on the absolute instead of the comparative motions of the pieces, and is, for that reason, defective, as Willis has pointed out in his admirable treatise *On the Principles of Mechanism.* Willis's classification is founded, in the first place, on comparative motion, as expressed by velocity ratio and directional relation, and in the second place, on the mode of connexion of the driver and follower. He divides the elementary combinations in mechanism into three classes, of which the characters are as follows:—

Class A: Directional relation constant; velocity ratio constant.
Class B: Directional relation constant; velocity ratio varying.
Class C: Directional relation changing periodically; velocity ratio constant or varying.

Each of those classes is subdivided by Willis into five divisions, of which the characters are as follows:—

| | | | |
|---|---|---|---|
| Division | A: | Connexion by | rolling contact. |
| ,, | B: | ,, | sliding contact. |
| ,, | C: | ,, | wrapping connectors. |
| ,, | D: | ,, | link-work. |
| ,, | E: | ,, | reduplication. |

In the present article the principle of Willis's classification is followed; but the arrangement is modified by taking the *mode of connexion* as the basis of the primary classification, and by removing the subject of connexion by reduplication to the section of aggregate combinations. This modified arrangement is adopted as being better suited than the original arrangement to the limits of an article in an encyclopædia; but it is not disputed that the original arrangement may be the best for a separate treatise.

49. *Rolling Contact—Smooth Wheels and Racks.*—In order that two pieces may move in *rolling contact*, it is necessary that each pair of points in the two pieces which touch each other should at the instant of contact be moving in the same direction with the same velocity. In the case of two *shifting* pieces this would involve equal and parallel velocities for all the points of each piece, so that there could be no rolling, and, in fact, the two pieces would move like one; hence, in the case of rolling contact, either one or both of the pieces must rotate.

The direction of motion of a point in a turning piece being perpendicular to a plane passing through its axis, the condition that each pair of points in contact with each other must move in the same direction leads to the following consequences:—

I. That, when both pieces rotate, their axes, and all their points of contact, lie in the same plane.

II. That, when one piece rotates and the other shifts, the axis of the rotating piece, and all the points of contact, lie in a plane perpendicular to the direction of motion of the shifting piece.

The condition that the velocity of each pair of points of contact must be equal leads to the following consequences:—

III. That the angular velocities of a pair of turning pieces in rolling contact must be inversely as the perpendicular distances of any pair of points of contact from the respective axes.

IV. That the linear velocity of a shifting piece in rolling contact with a turning piece is equal to the product of the angular velocity of the turning piece by the perpendicular distance from its axis to a pair of points of contact.

The *line of contact* is that line in which the points of contact are all situated. Respecting this line, the above principles III. and IV. lead to the following conclusions:—

V. That for a pair of turning pieces with parallel axes, and for a turning piece and a shifting piece, the line of contact is straight, and parallel to the axes or axis; and hence that the rolling surfaces are either plane or cylindrical (the term "cylindrical" including all surfaces generated by the motion of a straight line parallel to itself).

VI. That for a pair of turning pieces with intersecting axes the line of contact is also straight, and traverses the point of intersection of the axes; and hence that the rolling surfaces are conical, with a common apex (the term "conical" including all surfaces generated by the motion of a straight line which traverses a fixed point).

Turning pieces in rolling contact are called *smooth* or *toothless wheels*. Shifting pieces in rolling contact with turning pieces may be called *smooth* or *toothless racks*.

VII. In a pair of pieces in rolling contact every straight line traversing the line of contact is a line of connexion.

50. *Cylindrical Wheels and Smooth Racks.*—In designing cylindrical wheels and smooth racks, and determining their comparative motion, it is sufficient to consider a section of the pair of pieces made by a plane perpendicular to the axis or axes.

The points where axes intersect the plane of section are called *centres*; the point where the line of contact intersects it, the *point of contact*, or *pitch-point*; and the wheels are described as *circular*, *elliptical*, &c., according to the forms of their sections made by that plane.

When the point of contact of two wheels lies between their centres, they are said to be in *outside gearing*; when beyond their centres, in *inside gearing*, because the rolling surface of the larger wheel must in this case be turned inward or towards its centre.

From Principle III. of sect. 49 it appears that the angular velocity-ratio of a pair of wheels is the inverse ratio of the distances of the point of contact from the centres respectively.

For outside gearing that ratio is *negative*, because the wheels turn contrary ways; for inside gearing it is *positive*, because they turn the same way.

If the velocity ratio is to be constant, as in Willis's Class A, the wheels must be circular; and this is the most common form for wheels.

If the velocity ratio is to be variable, as in Willis's Class B, the figures of the wheels are a pair of *rolling curves*, subject to the condition that the distance between their *poles* (which are the centres of rotation) shall be constant.

The following is the geometrical relation which must exist between such a pair of curves. See fig. 10.

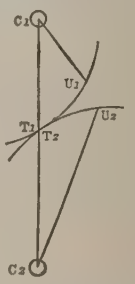

Fig. 10.

Let $C_1$, $C_2$ be the poles of a pair of rolling curves; $T_1$, $T_2$ any pair of points of contact; $U_1$, $U_2$ any other pair of points of contact. Then, for every possible pair of points of contact, the two following equations must be simultaneously fulfilled:—

$$\text{Sum of radii, } C_1U_1 + C_2U_2 - C_1T_1 + C_2T_2 = \text{constant};$$
$$\text{arc, } T_2U_2 = T_1U_1 \quad . \quad . \quad . \quad . \quad . \quad . \quad (17).$$

A condition equivalent to the above, and necessarily connected with it, is, that at each pair of points of contact the inclinations of the curves to their radii-vectores shall be equal and contrary; or, denoting by $r_1$, $r_2$ the radii-vectores at any given pair of points of contact, and $s$ the length of the equal arcs measured from a certain fixed pair of points of contact—

$$\frac{dr_2}{ds} = -\frac{dr_1}{ds} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (18);$$

which is the differential equation of a pair of rolling curves whose poles are at a constant distance apart.

For full details as to rolling curves, see Willis's work, already mentioned, and Clerk Maxwell's paper on Rolling Curves in the *Transactions of the Royal Society of Edinburgh*, 1849.

A rack, to work with a circular wheel, must be straight. To work with a wheel of any other figure, its section must be a rolling curve, subject to the condition that the perpendicular distance from the pole or centre of the wheel to a straight line parallel to the direction of the motion of the rack shall be constant. Let $r_1$ be the radius-vector of a point of contact on the wheel, $x_2$ the ordinate from the straight line before mentioned to the corresponding point of contact on the rack. Then

$$\frac{dx_2}{ds} = -\frac{dr_1}{ds} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (19)$$

is the differential equation of the pair of rolling curves.

To illustrate this subject, it may be mentioned that an ellipse rotating about one focus rolls completely round in outside gearing with an equal and similar ellipse also rotating about one focus, the distance between the axes of rotation being equal to the major axis of the ellipses, and the velocity ratio varying from $\frac{1+\text{eccentricity}}{1-\text{eccentricity}}$ to $\frac{1-\text{eccentricity}}{1+\text{eccentricity}}$; an hyperbola rotating about its further focus rolls in inside gearing, through a limited arc, with an equal and similar hyperbola rotating about its nearer focus, the distance between the axes of rotation being equal to the axis of the hyperbolas, and the velocity ratio varying between $\frac{\text{eccentricity}+1}{\text{eccentricity}-1}$ and unity; and a parabola rotating about its focus rolls with an equal and similar parabola, shifting parallel to its directrix.

51. *Conical or Bevel and Disk Wheels.*—From Principles III. and VI. of sect. 49 it appears that the angular velocities of a pair of wheels whose axes meet in a point are to each other inversely as the sines of the angles which the axes of the wheels make with the line of contact. Hence follows the following construction (figs. 11 and 12).—Let O be the apex or point of meeting of the two axes $OC_1$, $OC_2$. The angular velocity ratio being given, it is required to find the line of contact. On $OC_1$, $OC_2$ take lengths $OA_1$, $OA_2$, respectively proportional to the angular velocities of the pieces on whose axes they are taken. Complete the parallelogram $OA_1EA_2$; the diagonal OET will be the line of contact required.

When the velocity ratio is variable, the line of contact will shift its position in the plane $C_1OC_2$, and the wheels will be cones, with eccentric or irregular bases. In every case which occurs in practice, however, the velocity ratio is constant; the line of contact is constant in position, and the rolling surfaces of the wheels are regular circular cones (when they are called *bevel wheels*); or one of a pair of wheels may have a flat disk for its rolling surface, as $W_2$ in fig. 12, in which case it is a *disk wheel*. The rolling surfaces of actual wheels consist of frusta or zones of the complete cones or disks, as shown by $W_1$, $W_2$ in figs. 11 and 12.

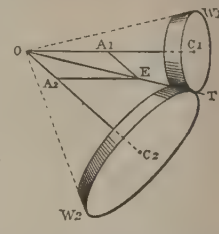

Fig. 11.

52. *Sliding Contact (lateral): Skew-Bevel Wheels.*—An hyperboloid of revolution is a surface resembling a sheaf or a dice box, generated by the rotation of a straight line round an axis from which it is at a constant distance, and to which it is inclined at a constant angle. If two such hyperboloids, equal or unequal, be placed in the closest possible contact, as in fig. 13, they will touch each other along one of the generating straight lines of each, which will form their line of contact, and will be inclined to the axes AG, BH in opposite directions. The axes will not be parallel, nor will they intersect each other.

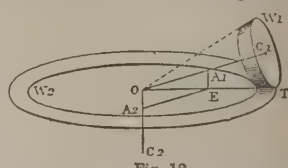

Fig. 12.

The motion of two such hyperboloids, turning in contact with each other, has hitherto been classed amongst cases of rolling contact; but that classification is not strictly correct, for, although the component velocities of a pair of points of contact in a direction at right angles to the line of contact are equal, still, as the axes are neither parallel to each other nor to the line of contact, the velocities of a pair of points of contact have components along the line of contact which are unequal, and their difference constitutes a *lateral sliding*.

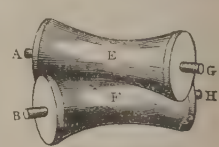

Fig. 13.

The directions and positions of the axes being given, and the required angular velocity ratio, the following construction serves to determine the line of contact, by whose rotation round the two axes respectively the hyperboloids are generated:—

In fig. 14, let $B_1C_1$, $B_2C_2$ be the two axes; $B_1B_2$ their common perpendicular. Through any point O in this common perpendicular draw $OA_1$ parallel to $B_1C_1$ and $OA_2$ parallel to $B_2C_2$; make those lines proportional to the angular velocities about the axes to which they are respectively parallel; complete the parallelogram $OA_1EA_2$, and draw the diagonal OE; divide $B_1B_2$ in D into two parts, *inversely* proportional to the angular velocities about the axes which they respectively adjoin; through D parallel to OE draw DT. This will be the line of contact.

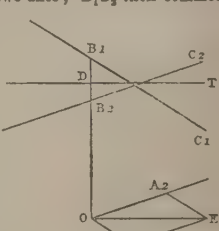

Fig. 14.

A pair of thin frusta of a pair of hyperboloids are used in practice to communicate motion between a pair of axes neither parallel nor intersecting, and are called *skew-bevel wheels*.

In skew-bevel wheels the properties of a line of connexion are not possessed by every line traversing the line of contact, but only by every line traversing the line of contact at right angles.

If the velocity ratio to be communicated were variable, the point D would alter its position, and the line DT its direction, at different periods of the motion, and the wheels would be hyperboloids of an eccentric or irregular cross-section; but forms of this kind are not used in practice.

53. *Sliding Contact (circular): Grooved Wheels.*—As the adhesion or friction between a pair of smooth wheels is seldom sufficient to prevent their slipping on each other, contrivances are used to increase their mutual hold. One of those consists in forming the rim of each wheel into a series of alternate ridges and grooves

parallel to the plane of rotation; it is applicable to cylindrical and bevel wheels, but not to skew-bevel wheels. The comparative motion of a pair of wheels so ridged and grooved is the same with that of a pair of smooth wheels in rolling contact, whose cylindrical or conical surfaces lie midway between the tops of the ridges and bottoms of the grooves, and those ideal smooth surfaces are called the *pitch surfaces* of the wheels.

The relative motion of the faces of contact of the ridges and grooves is a *rotatory sliding* or *grinding* motion, about the line of contact of the pitch-surfaces as an instantaneous axis.

Grooved wheels have hitherto been but little used.

54. *Sliding Contact (direct): Teeth of Wheels, their Number and Pitch.*—The ordinary method of connecting a pair of wheels, or a wheel and a rack, and the only method which insures the exact maintenance of a given numerical velocity ratio, is by means of a series of alternate ridges and hollows parallel or nearly parallel to the successive lines of contact of the ideal smooth wheels whose velocity ratio would be the same with that of the toothed wheels. The ridges are called *teeth*; the hollows, *spaces*. The teeth of the driver push those of the follower before them, and in so doing sliding takes place between them in a direction across their lines of contact.

The *pitch-surfaces* of a pair of toothed wheels are the ideal smooth surfaces which would have the same comparative motion by rolling contact that the actual wheels have by the sliding contact of their teeth. The *pitch-circles* of a pair of circular toothed wheels are sections of their pitch-surfaces, made for *spur-wheels* (that is, for wheels whose axes are parallel) by a plane at right angles to the axes, and for bevel wheels by a sphere described about the common apex. For a pair of skew-bevel wheels the pitch-circles are a pair of contiguous rectangular sections of the pitch-surfaces. The *pitch-point* is the point of contact of the pitch-circles.

The pitch-surface of a wheel lies intermediate between the points of the teeth and the bottoms of the hollows between them. That part of the acting surface of a tooth which projects beyond the pitch-surface is called the *face*; that part which lies within the pitch-surface, the *flank*.

Teeth, when not otherwise specified, are understood to be made in one piece with the wheel,—the material being generally cast-iron, brass, or bronze. Separate teeth, fixed into mortises in the rim of the wheel, are called *cogs*. A *pinion* is a small toothed wheel; a *trundle* is a pinion with cylindrical *staves* for teeth.

The radius of the pitch-circle of a wheel is called the *geometrical radius*; a circle touching the ends of the teeth is called the *addendum circle*, and its radius the *real radius*; the difference between these radii, being the projection of the teeth beyond the pitch-surface, is called the *addendum*.

The distance, measured along the pitch-circle, from the face of one tooth to the face of the next, is called the *pitch*. The pitch and the number of teeth in wheels are regulated by the following principles:—

I. In wheels which rotate continuously for one revolution or more, it is obviously necessary *that the pitch should be an aliquot part of the circumference*.

In wheels which reciprocate without performing a complete revolution this condition is not necessary. Such wheels are called *sectors*.

II. In order that a pair of wheels, or a wheel and a rack, may work correctly together, it is in all cases essential *that the pitch should be the same in each*.

III. Hence, in any pair of circular wheels which work together, the numbers of teeth in a complete circumference are directly as the radii and inversely as the angular velocities.

IV. Hence also, in any pair of circular wheels which rotate continuously for one revolution or more, the ratio of the numbers of teeth and its reciprocal the angular velocity ratio must be expressible in whole numbers.

From this principle arise problems of a kind which will be referred to in treating of *Trains of Mechanism*.

V. Let $n$, N be the respective numbers of teeth in a pair of wheels, N being the greater. Let $t$, T be a pair of teeth in the smaller and larger wheel respectively, which at a particular instant work together. It is required to find, first, how many pairs of teeth must pass the line of contact of the pitch-surfaces before $t$ and T work together again (let this number be called $a$); and, secondly, with how many different teeth of the larger wheel the tooth $t$ will work at different times (let this number be called $b$); thirdly, with how many different teeth of the smaller wheel the tooth T will work at different times (let this be called $c$).

CASE 1. If $n$ is a divisor of N,

$$a = N\,;\ b = \frac{N}{n}\,;\ c = 1 \quad . \ . \ . \ . \ . \ . \quad (20).$$

CASE 2. If the greatest common divisor of N and $n$ be $d$, a number less than $n$, so that $n = md$, $N = Md$; then

$$a = mN = Mn = Mmd\,;\ b = M\,;\ c = m \quad . \ . \ . \ . \quad (21).$$

CASE 3. If N and $n$ be prime to each other,

$$a = nN\,;\ b = N\,;\ c = n \quad . \ . \ . \ . \ . \ . \ . \quad (22)$$

It is considered desirable by millwrights, with a view to the preservation of the uniformity of shape of the teeth of a pair of wheels, that each given tooth in one wheel should work with as many different teeth in the other wheel as possible. They therefore study that the numbers of teeth in each pair of wheels which work together shall either be prime to each other, or shall have their greatest common divisor as small as is consistent with a velocity ratio suited for the purposes of the machine.

55. *Sliding Contact—Forms of the Teeth of Spur-wheels and Racks.*—A line of connexion of two pieces in sliding contact is a line perpendicular to their surfaces at a point where they touch. Bearing this in mind, the principle of the comparative motion of a pair of teeth belonging to a pair of spur-wheels, or to a spur-wheel and a rack, is found by applying the principles stated generally in sects. 46 and 47 to the case of parallel axes for a pair of spur-wheels, and to the case of an axis perpendicular to the direction of shifting for a wheel and rack.

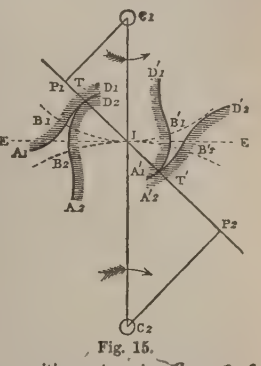

Fig. 15.

In fig. 15, let $C_1$, $C_2$ be the centres of a pair of spur-wheels; $B_1IB'_1$, $B_2IB'_2$ portions of their pitch-circles, touching at I, the pitch-point. Let the wheel 1 be the driver, and the wheel 2 the follower.

Let $D_1TB_1A_1$, $D_2TB_2A_2$ be the positions, at a given instant, of the acting surfaces of a pair of teeth in the driver and follower respectively, touching each other at T; the line of connexion of those teeth is $P_1P_2$, perpendicular to their surfaces at T. Let $C_1P_1$, $C_2P_2$ be perpendiculars let fall from the centres of the wheels on the line of contact. Then, by sect. 46, the angular velocity-ratio is

$$\frac{\alpha_2}{\alpha_1} = \frac{C_1P_1}{C_2P_2} \quad . \ . \ . \ . \ . \ . \ . \quad (23).$$

The following principles regulate the forms of the teeth and their relative motions:—

I. The angular velocity ratio due to the sliding contact of the teeth will be the same with that due to the rolling contact of the pitch-circles, if the line of connexion of the teeth cuts the line of centres at the pitch-point.

For, let $P_1P_2$ cut the line of centres at I; then, by similar triangles,

$$\alpha_1 : \alpha_2 :: C_2P_2 : C_1P_1 :: IC_2 :: IC_1 \quad . \ . \ . \quad (24);$$

which is also the angular velocity ratio due to the rolling contact of the circles $B_1IB'_1$, $B_2IB'_2$.

This principle determines the *forms* of all teeth of spur-wheels. It also determines the forms of the teeth of straight racks, if one of the centres be removed, and a straight line $EIE'$, parallel to the direction of motion of the rack and perpendicular to $C_1C_2$, be substituted for a pitch-circle.

II. The component of the velocity of the point of contact of the teeth T along the line of connexion is

$$\alpha_1 \,.\, C_1P_1 = \alpha_2 \,.\, C_2P_2 \quad . \ . \ . \ . \ . \ . \quad (25).$$

III. The relative velocity perpendicular to $P_1P_2$ of the teeth at their point of contact,—that is, their *velocity of sliding* on each other,—is found by supposing one of the wheels, such as 1, to be fixed, the line of centres $C_1C_2$ to rotate backwards round $C_1$ with the angular velocity $\alpha_1$, and the wheel 2 to rotate round $C_2$ as before, with the angular velocity $\alpha_2$ relatively to the line of centres $C_1C_2$, so as to have the same motion as if its pitch-circle *rolled* on the pitch-circle of the first wheel. Thus the *relative* motion of the wheels is unchanged; but 1 is considered as fixed, and 2 has the *total motion* given by the principles of sects. 37 and 38,—that is, a rotation about the instantaneous axis I, with the angular velocity $\alpha_1 + \alpha_2$. Hence the *velocity of sliding* is that due to this rotation about I, with the radius IT; that is to say, its value is

$$(\alpha_1 + \alpha_2) \,.\, IT \quad . \ . \ . \ . \ . \ . \ . \quad (26);$$

so that it is greater the farther the point of contact is from the line of centres; and at the instant when that point passes the line of centres, and coincides with the *pitch-point*, the velocity of sliding is null, and the action of the teeth is, for the instant, that of rolling contact.

IV. The *path of contact* is the line traversing the various positions of the point T. If the line of connexion preserves always the same

position, the path of contact coincides with it, and is straight; in other cases the path of contact is curved.

It is divided by the pitch-point I into two parts,—the *arc* or *line of approach* described by T in approaching the line of centres, and the *arc* or *line of recess* described by T after having passed the line of centres.

During the *approach*, the *flank* $D_1B_1$ of the driving tooth drives the *face* $D_2B_2$ of the following tooth, and the teeth are sliding *towards* each other. During the *recess* (in which the position of the teeth is exemplified in the figure by curves marked with accented letters), the *face* $B'_1A'_1$ of the driving tooth drives the *flank* $B'_2A'_2$ of the following tooth, and the teeth are sliding *from* each other.

The path of contact is bounded where the approach commences by the addendum-circle of the follower, and where the recess terminates by the addendum-circle of the driver. The length of the path of contact should be such that there shall always be at least one pair of teeth in contact; and it is better still to make it so long that there shall always be at least two pairs of teeth in contact.

V. The *obliquity* of the action of the teeth is the angle $EIT = IC_1P_1 = IC_2P_2$.

In practice it is found desirable that the mean value of the obliquity of action during the contact of teeth should not exceed 15°, nor the maximum value 30°.

It is unnecessary to give separate figures and demonstrations for inside gearing. The only modification required in the formulæ is, that in equation 26 the *difference* of the angular velocities should be substituted for their sum.

56. *Involute Teeth.*—The simplest form of tooth which fulfils the conditions of sect. 55 is obtained in the following manner (see fig. 16). Let $C_1$, $C_2$ be the centres of two wheels, $B_1IB'_1$, $B_2IB'_2$ their pitch-circles, I the pitch-point; let the obliquity of action of the teeth be constant, so that the same straight line $P_1IP_2$ shall represent at once the constant line of connexion of teeth and the path of contact. Draw $C_1P_1$, $C_2P_2$ perpendicular to $P_1IP_2$, and with those lines as radii describe about the centres of the wheels the circles $D_1D'_1$, $D_2D'_2$, called *base-circles*. It is evident that the radii of the base-circles bear to each other the same proportions as the radii of the pitch-circles, and also that

$$\left.\begin{aligned} C_1P_1 &= IC_1 \cdot \cos \text{obliquity} \\ C_2P_2 &= IC_2 \cdot \cos \text{obliquity} \end{aligned}\right\} \quad \ldots\ldots \quad (27).$$

(The obliquity which is found to answer best in practice is about $14\frac{1}{2}°$; its cosine is about $\frac{1}{2}\frac{1}{2}$, and its sine about $\frac{1}{4}$. These values, though not absolutely exact, are near enough to the truth for practical purposes.)

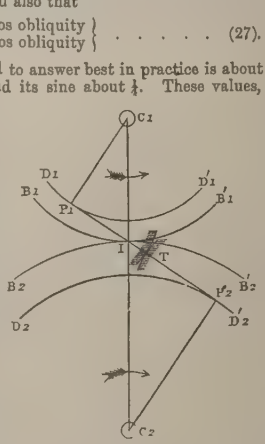

Fig. 16.

Suppose the base-circles to be a pair of circular pulleys connected by means of a cord whose course from pulley to pulley is $P_1IP_2$. As the line of connexion of those pulleys is the same with that of the proposed teeth, they will rotate with the required velocity ratio. Now, suppose a tracing point T to be fixed to the cord, so as to be carried along the path of contact $P_1IP_2$, that point will trace on a plane rotating along with the wheel 1 part of the involute of the base-circle $D_1D'_1$, and on a plane rotating along with the wheel 2 part of the involute of the base-circle $D_2D'_2$; and the two curves so traced will always touch each other in the required point of contact T, and will therefore fulfil the condition required by Principle I. of sect. 55.

Consequently, one of the forms suitable for the teeth of wheels is the involute of a circle; and the obliquity of the action of such teeth is the angle whose cosine is the ratio of the radius of their base-circle to that of the pitch-circle of the wheel.

All involute teeth of the same pitch work smoothly together.

To find the length of the path of contact on either side of the pitch-point I, it is to be observed that the distance between the fronts of two successive teeth, as measured along $P_1IP_2$, is less than the pitch in the ratio of cos obliquity : 1; and consequently that, if distances equal to the pitch be marked off either way from I towards $P_1$ and $P_2$ respectively, as the extremities of the path of contact, and if, according to Principle IV. of sect. 55, the addendum-circles be described through the points so found, there will always be at least two pairs of teeth in action at once. In practice it is usual to make the path of contact somewhat longer, viz., about $2\frac{1}{10}$th times the pitch; and with this length of path, and the obliquity already mentioned of $14\frac{1}{2}°$, the addendum is about $\frac{1}{10}$ths of the pitch.

The teeth of a *rack*, to work correctly with wheels having involute teeth, should have plane surfaces perpendicular to the line of connexion, and consequently making with the direction of motion of the rack angles equal to the complement of the obliquity of action.

57. *Teeth for a given Path of Contact—Mr Sang's Method.*—In the preceding section the form of the teeth is found by assuming a figure for the path of contact, viz., the straight line. Any other convenient figure may be assumed for the path of contact, and the corresponding forms of the teeth found by determining what curves a point T, moving along the assumed path of contact, will trace on two disks rotating round the centres of the wheels with angular velocities bearing that relation to the component velocity of T along TI, which is given by Principle II. of sect. 55, and by equation 25. This method of finding the forms of the teeth of wheels forms the subject of an elaborate and most interesting treatise by Mr Edward Sang.

All wheels having teeth of the same pitch, traced from the same path of contact, work correctly together, and are said to belong to the *same set*.

58. *Teeth traced by Rolling Curves.*—If any curve R (fig. 17) be rolled on the inside of the pitch-circle BB of a wheel, it appears, from sect. 37, that the instantaneous axis of the rolling curve at any instant will be at the point I, where it touches the pitch-circle for the moment, and that consequently the line AT, traced by a tracing-point T, fixed to the rolling curve upon the plane of the wheel, will be everywhere perpendicular to the straight line TI; so that the traced curve AT will be suitable for the flank of a tooth, in which T is the point of contact corresponding to the position I of the pitch-point. If the same rolling curve R, with the same tracing-point T, be rolled on the *outside* of any other pitch-circle, it will have the *face* of a tooth suitable to work with the *flank* AT.

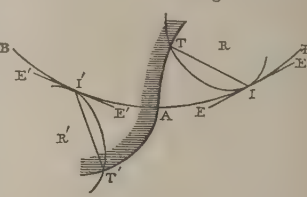

Fig. 17.

In like manner, if either the same or any other rolling curve R′ be rolled the opposite way, on the *outside* of the pitch-circle BB, so that the tracing point T′ shall start from A, it will trace the *face* AT′ of a tooth suitable to work with a *flank* traced by rolling the same curve R′ with the same tracing-point T′ *inside* any other pitch-circle.

The figure of the *path of contact* is that traced on a fixed plane by the tracing-point, when the rolling curve is rotated in such a manner as always to touch a fixed straight line EIE (or E′IE′, as the case may be) at a fixed point I (or I′).

If the same rolling curve and tracing point be used to trace both the faces and the flanks of the teeth of a number of wheels of different sizes but of the same pitch, all those wheels will work correctly together, and will form a *set*. The teeth of a *rack*, of the same set, are traced by rolling the rolling curve on both sides of a straight line.

The teeth of wheels of any figure, as well as of circular wheels, may be traced by rolling curves on their pitch-surfaces; and all teeth of the same pitch, traced by the same rolling curve with the same tracing-point, will work together correctly if their pitch-surfaces are in rolling contact.

59. *Epicycloidal Teeth.*—The most convenient rolling curve is the circle. The path of contact which it traces is identical with itself; and the flanks of the teeth are internal and their faces external epicycloids for wheels, and both flanks and faces are cycloids for a rack.

For a pitch-circle of twice the radius of the rolling or *describing* circle (as it is called) the internal epicycloid is a straight line, being, in fact, a diameter of the pitch circle, so that the flanks of the teeth for such a pitch-circle are planes radiating from the axis. For a smaller pitch-circle the flanks would be convex and *incurved* or *under-cut*, which would be inconvenient; therefore the smallest wheel of a set should have its pitch-circle of twice the radius of the describing circle, so that the flanks may be either straight or concave

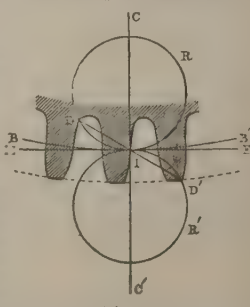

Fig. 18.

In fig. 18, let BB′ be part of the pitch-circle of a wheel with epicycloidal teeth; CIC′ the line of centres; I the pitch-point · EIE

a straight tangent to the pitch-circle at that point; R the internal and R′ the equal external describing circles, so placed as to touch the pitch-circle and each other at I. Let DID′ be the path of contact, consisting of the arc of approach DI and the arc of recess ID′. In order that there may always be at least two pairs of teeth in action, each of those arcs should be equal to the pitch.

The obliquity of the action in passing the line of centres is nothing; the maximum obliquity is the angle EID = ETD: and the mean obliquity is one-half of that angle.

It appears from experience that the mean obliquity should not exceed 15°; therefore the maximum obliquity should be about 30°; therefore the equal arcs DI and ID′ should each be one-sixth of a circumference; therefore the circumference of the describing circle should be *six times the pitch*.

It follows that the smallest pinion of a set in which pinion the flanks are straight should have twelve teeth.

60. *Nearly Epicycloidal Teeth—Willis's Method.*—To facilitate the drawing of epicycloidal teeth in practice, Willis has shown how to approximate to their figure by means of two circular arcs,—one concave, for the flank, and the other convex, for the face,—and each having for its radius the *mean* radius of curvature of the epicycloidal arc. Willis's formulæ are founded on the following properties of epicycloids:—

Let R be the radius of the pitch-circle; $r$ that of the describing circle; $\theta$ the angle made by the normal TI to the epicycloid at a given point T, with a tangent to the circle at I; that is, the obliquity of the action at T.

Then the radius of curvature of the epicycloid at T is—

$$\left.\begin{aligned} \text{For an internal epicycloid, } \rho &= 4r\sin\theta\,\frac{R-r}{R-2r} \\ \text{For an external epicycloid, } \rho' &= 4r\sin\theta\,\frac{R+r}{R+2r} \end{aligned}\right\} \quad . \quad . \quad . \quad . \quad (28).$$

Also, to find the position of the centres of curvature relatively to the pitch-circle, we have, denoting the chord of the describing circle TI by $c$, $c = 2r\sin\theta$; and therefore

$$\left.\begin{aligned} \text{For the flank, } \rho - c &= 2r\sin\theta\,\frac{R}{R-2r} \\ \text{For the face, } \rho' - c &= 2r\sin\theta\,\frac{R}{R+2r} \end{aligned}\right\} \quad . \quad . \quad (29).$$

For the proportions approved of by Willis, $\sin\theta = \frac{1}{4}$ nearly; $r = p$ (the pitch) nearly; $c = \frac{1}{2}p$ nearly; and, if N be the number of teeth in the wheel, $\frac{r}{R} = \frac{6}{N}$ nearly; therefore, approximately,

$$\left.\begin{aligned} \rho - c &= \frac{p}{2}\cdot\frac{N}{N-12} \\ \rho' - c &= \frac{p}{2}\cdot\frac{N}{N+12} \end{aligned}\right\} \quad . \quad . \quad . \quad . \quad . \quad (30).$$

Hence the following construction (fig. 19). Let BB be part of the pitch-circle, and $a$ the point where a tooth is to cross it. Set off $ab = ac = \frac{1}{2}p$. Draw radii $bd$, $ce$; draw $fb$, $cg$, making angles of 75½° with those radii. Make $bf = \rho' - c$, $cg = \rho - c$. From $f$, with the radius $fa$, draw the circular arc $ah$; from $g$, with the radius $ga$, draw the circular arc $ak$. Then $ah$ is the face and $ak$ the flank of the tooth required.

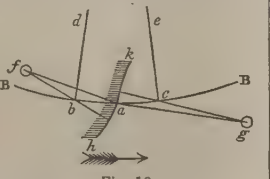

Fig. 19.

To facilitate the application of this rule, Willis published tables of $\rho - c$ and $\rho' - c$, and invented an instrument called the "odontograph."

61. *Trundles and Pin-Wheels.*—If a wheel or trundle have cylindrical pins or staves for teeth, the faces of the teeth of a wheel suitable for driving it are described by first tracing external epicycloids, by rolling the pitch-circle of the pin-wheel or trundle on the pitch-circle of the driving-wheel, with the centre of a stave for a tracing-point, and then drawing curves parallel to, and within the epicycloids, at a distance from them equal to the radius of a stave. Trundles having only six staves will work with large wheels.

62. *Backs of Teeth and Spaces.*—Toothed wheels being in general intended to rotate either way, the *backs* of the teeth are made similar to the fronts. The *spaces* between two teeth, measured on the pitch-circle, is made about $\frac{1}{11}$th part wider than the thickness of the tooth on the pitch-circle; that is to say,

Thickness of tooth $= \frac{5}{11}$ pitch;
Width of space $= \frac{6}{11}$ pitch.

The difference of $\frac{1}{11}$ of the pitch is called the *back-lash*. The clearance allowed between the points of teeth and the bottoms of the spaces between the teeth of the other wheel is about $\frac{1}{10}$th of the pitch.

63. *Stepped and Helical Teeth.*—Hooke invented the making of the fronts of teeth in a series of steps with a view to increase the smoothness of action. A wheel thus formed resembles in shape a series of equal and similar toothed disks placed side by side, with the teeth of each a little behind those of the preceding disk. He also invented, with the same object, teeth whose fronts, instead of being parallel to the line of contact of the pitch-circles, cross it obliquely, so as to be of a screw-like or helical form. In wheel-work of this kind the contact of each pair of teeth commences at the foremost end of the helical front, and terminates at the aftermost end; and the helix is of such a pitch that the contact of one pair of teeth shall not terminate until that of the next pair has commenced.

Stepped and helical teeth have the desired effect of increasing the smoothness of motion, but they require more difficult and expensive workmanship than common teeth; and helical teeth are, besides, open to the objection that they exert a laterally oblique pressure, which tends to increase resistance, and unduly strain the machinery.

64. *Teeth of Bevel-Wheels.*—The acting surfaces of the teeth of bevel-wheels are of the conical kind, generated by the motion of a line passing through the common apex of the pitch-cones, while its extremity is carried round the outlines of the cross section of the teeth made by a sphere described about that apex.

The operations of describing the exact figures of the teeth of bevel-wheels, whether by involutes or by rolling curves, are in every respect analogous to those for describing the figures of the teeth of spur-wheels, except that in the case of bevel-wheels all those operations are to be performed on the surface of a sphere described about the apex instead of on a plane, substituting *poles* for *centres*, and *great circles* for *straight lines*.

In consideration of the practical difficulty, especially in the case of large wheels, of obtaining an accurate spherical surface, and of drawing upon it when obtained, the following approximate method, proposed originally by Tredgold, is generally used:—

Let O (fig. 20) be the common apex of a pair of bevel-wheels; $OB_1I$, $OB_2I$ their pitch cones; $OC_1$, $OC_2$ their axes; OI their line of contact. Perpendicular to OI draw $A_1IA_2$, cutting the axes in $A_1$, $A_2$; make the outer rims of the patterns and of the wheels portions of the cones $A_1B_1I$, $A_2B_2I$, of which the narrow zones occupied by the teeth will be sufficiently near to a spherical surface described about O for practical purposes. To find the figures of the teeth, draw on a flat surface circular arcs $ID_1$, $ID_2$, with the radii $A_1I$, $A_2I$; those arcs will be the *developments* of arcs of the pitch-circles $B_1I$, $B_2I$, when the conical surfaces $A_1B_1I$, $A_2B_2I$ are spread out flat. Describe the figures of teeth for the developed arcs as for a pair of spur-wheels; then wrap the developed arcs on the cones, so as to make them coincide with the pitch-circles, and trace the teeth on the conical surfaces.

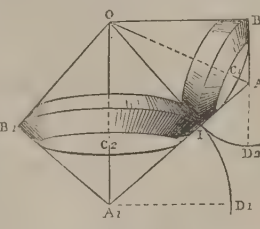

Fig. 20.

65. *Teeth of Skew-Bevel Wheels.*—The crests of the teeth of a skew-bevel wheel are parallel to the generating straight line of the hyperboloidal pitch-surface; and the transverse sections of the teeth at a given pitch-circle are similar to those of the teeth of a bevel-wheel whose pitch-surface is a cone touching the hyperboloidal surface at the given circle.

66. *Cams.*—A *cam* is a single tooth, either rotating continuously or oscillating, and driving a sliding or turning piece either constantly or at intervals. All the principles which have been stated in sect. 55 as being applicable to teeth are applicable to cams; but in designing cams it is not usual to determine or take into consideration the form of the ideal pitch-surface, which would give the same comparative motion by rolling contact that the cam gives by sliding contact.

67. *Screws.*—The figure of a screw is that of a convex or concave cylinder, with one or more helical projections, called *threads*, winding round it. Convex and concave screws are distinguished technically by the respective names of *male* and *female*; a short concave screw is called a *nut*; and when a *screw* is spoken of without qualification a *convex* screw is usually understood.

The relation between the *advance* and the *rotation*, which compose the motion of a screw working in contact with a fixed screw or helical guide, has already been demonstrated in sect. 41; and the same relation exists between the magnitudes of the rotation of a screw about a fixed axis and the advance of a shifting nut in which it rotates. The advance of the nut takes place in the opposite direction to that of the advance of the screw in the case in which the nut is fixed. The *pitch* or *axial pitch* of a screw has the meaning assigned to it in that section, viz., the distance, measured

parallel to the axis, between the corresponding points in two successive turns of the *same thread*. If, therefore, the screw has several equidistant threads, the true pitch is equal to the *divided axial pitch*, as measured between two adjacent threads, multiplied by the number of threads.

If a helix be described round the screw, crossing each turn of the thread at right angles, the distance between two corresponding points on two successive turns of the same thread, measured along this *normal helix*, may be called the *normal pitch*; and when the screw has more than one thread the normal pitch from thread to thread may be called the *normal divided pitch*.

The distance from thread to thread, measured on a circle described about the axis of the screw, called the pitch-circle, may be called the *circumferential pitch*; for a screw of one thread it is one circumference; for a screw of $n$ threads, $\frac{\text{one circumference}}{n}$.

Let $r$ denote the radius of the pitch circle;

$n$ the number of threads;

$\theta$ the obliquity of the threads to the pitch circle, and of the normal helix to the axis;

$$\left.\begin{aligned} P_a \\ \frac{P_a}{n} = p_a \end{aligned}\right\} \text{the axial} \begin{cases} \text{pitch,} \\ \text{divided pitch;} \end{cases}$$

$$\left.\begin{aligned} P_n \\ \frac{P_n}{n} = p_n \end{aligned}\right\} \text{the normal} \begin{cases} \text{pitch,} \\ \text{divided pitch;} \end{cases}$$

$P_c$ the circumferential pitch;

then

$$\left.\begin{aligned} p_c &= p_a \cot\theta = p_n \cos\theta = \frac{2\pi r}{n}. \\ p_n &= p_n \sec\theta = p_c \tan\theta = \frac{2\pi r \tan\theta}{n} \\ p_n &= p_c \sin\theta = p_a \cos\theta = \frac{2\pi r \sin\theta}{n} \end{aligned}\right\} \quad . \quad . \quad (31).$$

If a screw rotates, the number of threads which pass a fixed point in one revolution is the number of threads in the screw.

A pair of convex screws, each rotating about its axis, are used as an elementary combination to transmit motion by the sliding contact of their threads. Such screws are commonly called *endless screws*. At the point of contact of the screws their threads must be parallel; and their line of connexion is the common perpendicular to the acting surfaces of the threads at their point of contact. Hence the following principles:—

I. If the screws are both right-handed or both left-handed, the angle between the directions of their axes is the sum of their obliquities; if one is right-handed and the other left-handed, that angle is the difference of their obliquities.

II. The normal pitch for a screw of one thread, and the normal divided pitch for a screw of more than one thread, must be the same in each screw.

III. The angular velocities of the screws are inversely as their numbers of threads.

Hooke's wheels with oblique or helical teeth are in fact screws of many threads, and of large diameters as compared with their lengths.

The ordinary position of a pair of endless screws is with their axes at right angles to each other. When one is of considerably greater diameter than the other, the larger is commonly called in practice a *wheel*, the name *screw* being applied to the smaller only; but they are nevertheless both screws in fact.

To make the teeth of a pair of endless screws fit correctly and work smoothly, a hardened steel screw is made of the figure of the smaller screw, with its thread or threads notched so as to form a cutting tool; the larger screw, or "wheel," is cast approximately of the required figure; the larger screw and the steel screw are fitted up in their proper relative position, and made to rotate in contact with each other by turning the steel screw, which cuts the threads of the larger screw to their true figure.

68. *Coupling of Parallel Axes—Oldham's Coupling.*—A *coupling* is a mode of connecting a pair of shafts so that they shall rotate in the same direction with the same mean angular velocity. If the axes of the shafts are in the same straight line, the coupling consists in so connecting their contiguous ends that they shall rotate as one piece; but if the axes are not in the same straight line combinations of mechanism are required. A coupling for parallel shafts which acts by *sliding contact* was invented by Oldham, and is represented in fig. 21. $C_1$, $C_2$ are the axes of the two parallel shafts; $D_1$, $D_2$ two disks facing each other, fixed on the ends of the two shafts respectively; $E_1E_1$ a bar sliding in a diametral groove in the face of $D_1$; $E_2E_2$ a bar sliding in a diametral groove in the face of $D_2$: those bars are fixed together at A, so as to form a rigid cross. The angular velocities of the two disks and of the cross are all equal at every instant; the middle point of the cross, at A, revolves in the dotted circle described upon the line of centres $C_1C_2$ as a diameter twice for each turn of the disks and cross; the instantaneous axis of rotation of the cross at any instant is at I, the point in the circle $C_1C_2$ diametrically opposite to A.

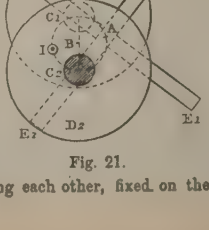

Fig. 21.

Oldham's coupling may be used with advantage where the axes of the shafts are intended to be as nearly in the same straight line as is possible, but where there is some doubt as to the practicability or permanency of their exact continuity.

69. *Wrapping Connectors—Belts, Cords, and Chains.*—Flat belts of leather or of gutta percha, round cords of catgut, hemp, or other material, and metal chains are used as wrapping connectors to transmit rotatory motion between pairs of pulleys and drums.

*Belts* (the most frequently used of all wrapping connectors) require nearly cylindrical pulleys. A belt tends to move towards that part of a pulley whose radius is greatest; pulleys for belts, therefore, are slightly swelled in the middle, in order that the belt may remain on a pulley, unless forcibly shifted. A belt when in motion is shifted off a pulley, or from one pulley on to another of equal size alongside of it, by pressing against that part of the belt which is moving *towards* the pulley.

*Cords* require either cylindrical drums with ledges or grooved pulleys.

*Chains* require pulleys or drums, grooved, notched, and toothed, so as to fit the links of the chain.

Wrapping connectors for communicating continuous motion are endless.

Wrapping connectors for communicating reciprocating motion have usually their ends made fast to the pulleys or drums which they connect, and which in this case may be sectors.

The line of connexion of two pieces connected by a wrapping connector is the centre line of the belt, cord, or chain; and the comparative motions of the pieces are determined by the principles of sect. 46 if both pieces turn, and of sect. 47 if one turns and the other shifts, in which latter case the motion must be reciprocating.

The *pitch-line* of a pulley or drum is a curve to which the line of connexion is always a tangent; that is to say, it is a curve parallel to the acting surface of the pulley or drum, and distant from it by half the thickness of the wrapping connector.

Pulleys and drums for communicating a constant velocity ratio are circular. The *effective radius*, or radius of the pitch-circle of a circular pulley or drum, is equal to the real radius added to half the thickness of the connector. The angular velocities of a pair of connected circular pulleys or drums are inversely as the effective radii.

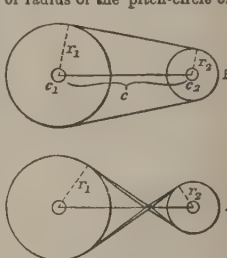

Fig. 22.

A *crossed* belt, as in fig. 22, A, reverses the direction of the rotation communicated; an *uncrossed* belt, as in fig. 22, B, preserves that direction.

The *length* L of an endless belt connecting a pair of pulleys whose effective radii are $r_1$, $r_2$, with parallel axes whose distance apart is C, is given by the following formulæ, in each of which the first term, containing the radical, expresses the length of the straight parts of the belt, and the remainder of the formula the length of the curved parts.

For a crossed belt,—

$$L = 2\sqrt{c^2 - (r_1 + r_2)^2} + (r_1 + r_2)\left(\pi - 2\sin^{-1}\frac{r_1 + r_2}{c}\right) \quad (32, A);$$

and for an uncrossed belt,—

$$L = 2\sqrt{c^2 - (r_1 - r_2)^2} + \pi(r_1 + r_2) + 2(r_1 - r_2)\sin^{-1}\frac{r_1 - r_2}{c} \quad (32, B);$$

in which $r_1$ is the greater radius, and $r_2$ the less.

When the axes of a pair of pulleys are not parallel, the pulleys should be so placed that the part of the belt which is *approaching* each pulley shall be in the plane of the pulley.

70. *Speed-Cones* (see fig. 23).—A pair of speed-cones is a contrivance for varying and adjusting the velocity ratio communicated between a pair of parallel shafts by means of a belt. The speed-cones are either continuous cones or conoids, as A, B, whose velocity ratio can be varied gradually while they are in motion by shifting the belt, or sets of pulleys whose radii vary by steps, as C, D, in which case the velocity ratio can be changed by shifting the belt from one pair of pulleys to another.

In order that the belt may fit accurately in every possible position on a pair of speed-cones, the quantity L must be constant, in equations 32, A, or 32, B, according as the belt is crossed or uncrossed.

For a *crossed* belt, as in A and C, fig. 23, L depends solely on $c$ and on $r_1+r_2$. Now $c$ is constant because the axes are parallel; therefore the *sum of the radii* of the pitch-circles connected in every position of the belt is to be constant. That condition is fulfilled by a pair of continuous cones generated by the revolution of two straight lines inclined opposite ways to their respective axes at equal angles.

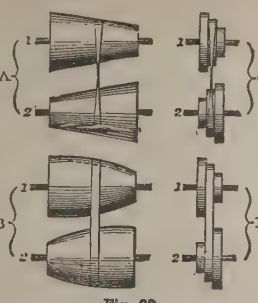

Fig. 23.

For an uncrossed belt, the quantity L in equation 32, B is to be made constant. The exact fulfilment of this condition requires the solution of a transcendental equation; but it may be fulfilled with accuracy sufficient for practical purposes by using, instead of 32, B, the following *approximate* equation:—

$$\text{L nearly} = 2c + \pi(r_1+r_2) + \frac{(r_1-r_2)^2}{c} \quad . \quad . \quad . \quad (33).$$

The following is the most convenient practical rule for the application of this equation:—

Let the speed-cones be equal and similar conoids, as in B, fig. 23, but with their large and small ends turned opposite ways. Let $r_1$ be the radius of the large end of each, $r_2$ that of the small end, $r_0$ that of the middle; and let $v$ be the *sagitta*, measured perpendicular to the axes, of the arc by whose revolution each of the conoids is generated, or, in other words, the *bulging* of the conoids in the middle of their length. Then

$$v = r_0 - \frac{r_1+r_2}{2} = \frac{(r_1-r_2)^2}{2\pi c} \quad . \quad . \quad . \quad . \quad . \quad (34).$$

$2\pi = 6{\cdot}2832$; but 6 may be used in most practical cases without sensible error.

The radii at the middle and end being thus determined, make the generating curve an arc either of a circle or of a parabola.

71. *Linkwork in General.*—The pieces which are connected by linkwork, if they rotate or oscillate, are usually called *cranks*, *beams*, and *levers*. The *link* by which they are connected is a rigid rod or bar, which may be straight or of any other figure; the straight figure, being the most favourable to strength, is always used when there is no special reason to the contrary. The link is known by various names under various circumstances, such as *coupling-rod*, *connecting-rod*, *crank-rod*, *eccentric-rod*, &c. It is attached to the pieces which it connects by two pins, about which it is free to turn. The effect of the link is to maintain the distance between the axes of those pins invariable; hence the common perpendicular of the axes of the pins is *the line of connexion*, and its extremities may be called the *connected points*. In a turning piece, the perpendicular let fall from its connected point upon its axis of rotation is the *arm* or *crank-arm*.

The axes of rotation of a pair of turning pieces connected by a link are almost always parallel, and perpendicular to the line of connexion; in which case the angular velocity ratio at any instant is the reciprocal of the ratio of the common perpendiculars let fall from the line of connexion upon the respective axes of rotation.

If at any instant the direction of one of the crank-arms coincides with the line of connexion, the common perpendicular of the line of connexion and the axis of that crank-arm vanishes, and the directional relation of the motions becomes indeterminate. The position of the connected point of the crank-arm in question at such an instant is called a *dead-point*. The velocity of the other connected point at such an instant is null, unless it also reaches a dead-point at the same instant, so that the line of connexion is in the plane of the two axes of rotation, in which case the velocity ratio is indeterminate. Examples of dead-points, and of the means of preventing the inconvenience which they tend to occasion, will appear in the sequel.

72. *Coupling of Parallel Axes.*—Two or more parallel shafts (such as those of a locomotive engine, with two or more pairs of driving wheels) are made to rotate with constantly equal angular velocities by having equal cranks, which are maintained parallel by a coupling-rod of such a length that the line of connexion is equal to the distance between the axes. The cranks pass their dead-points simultaneously. To obviate the unsteadiness of motion which this tends to cause, the shafts are provided with a second set of cranks at right angles to the first, connected by means of a similar coupling-rod, so that one set of cranks pass their dead points at the instant when the other set are farthest from theirs.

73. *Comparative Motion of Connected Points.*—As the link is a rigid body, it is obvious that its action in communicating motion may be determined by finding the comparative motion of the connected points, according to the principles laid down in §§ 71, 78, pp. 690, 692, and this is often the most convenient method of proceeding.

If a connected point belongs to a turning piece, the direction of its motion at a given instant is perpendicular to the plane containing the axis and crank-arm of the piece. If a connected point belongs to a shifting piece, the direction of its motion at any instant is given, and a plane can be drawn perpendicular to that direction.

The line of intersection of the planes perpendicular to the paths of the two connected points at a given instant is the *instantaneous axis of the link* at that instant; and the *velocities of the connected points are directly as their distances from that axis.*

In drawing on a plane surface, the two planes perpendicular to the paths of the connected points are represented by two lines (being their sections by a plane normal to them), and the instantaneous axis by a point (fig. 24); and, should the length of the two lines render it impracticable to produce them until they actually intersect, the velocity ratio of the connected points may be found by the principle that it is equal to the ratio of the segments which a line parallel to the line of connexion cuts off from any two lines drawn from a given point, perpendicular respectively to the paths of the connected points.

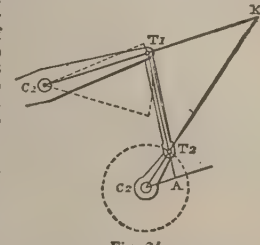

Fig. 24.

To illustrate this by one example. Let $C_1$ be the axis, and $T_1$ the connected point of the beam of a steam-engine; $T_1T_2$ the connecting or crank-rod; $T_2$ the other connected point, and the centre of the crank-pin; $C_2$ the axis of the crank and its shaft. Let $v_1$ denote the velocity of $T_1$ at any given instant; $v_2$ that of $T_2$. To find the ratio of these velocities, produce $C_1T_1$, $C_2T_2$, till they intersect in K; K is the instantaneous axis of the connecting rod, and the velocity ratio is

$$v_1 : v_2 :: KT_1 : KT_2. \quad . \quad . \quad . \quad . \quad . \quad . \quad (35).$$

Should K be inconveniently far off, draw any triangle with its sides respectively parallel to $C_1T_1$, $C_2T_2$, and $T_1T_2$; the ratio of the two sides first mentioned will be the velocity ratio required. For example, draw $C_2A$ parallel to $C_1T_1$, cutting $T_1T_2$ in A; then

$$v_1 : v_2 :: C_2A : C_2T_2 \quad . \quad . \quad . \quad . \quad . \quad (36).$$

74. *Eccentric.*—An eccentric circular disk fixed on a shaft, and used to give a reciprocating motion to a rod, is in effect a crank-pin of sufficiently large diameter to surround the shaft, and so to avoid the weakening of the shaft which would arise from bending it so as to form an ordinary crank. The centre of the eccentric is its connected point; and its eccentricity, or the distance from that centre to the axis of the shaft, is its crank-arm.

An eccentric may be made capable of having its eccentricity altered by means of an adjusting screw, so as to vary the extent of the reciprocating motion which it communicates.

75. *Reciprocating Pieces—Stroke—Dead-Points.*—The distance between the extremities of the path of the connected point in a reciprocating piece (such as the piston of a steam-engine) is called the *stroke* or *length of stroke* of that piece. When it is connected with a continuously turning piece (such as the crank of a steam-engine) the ends of the stroke of the reciprocating piece correspond to the *dead-points* of the path of the connected point of the turning piece, where the line of connexion is continuous with or coincides with the crank-arm.

Let S be the length of stroke of the reciprocating piece, L the length of the line of connexion, and R the crank-arm of the continuously turning piece. Then, if the two ends of the stroke be in one straight line with the axis of the crank,

$$S = 2R \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (37);$$

and if these ends be not in one straight line with that axis, then S, L−R, and L+R, are the three sides of a triangle, having the angle opposite S at that axis; so that, if $\theta$ be the supplement of the arc between the dead-points,

$$\left.\begin{aligned} S^2 &= 2(L^2+R^2) - 2(L^2-R^2)\cos\theta \\ \cos\theta &= \frac{2L^2+2R^2-S^2}{2(L^2-R^2)} \end{aligned}\right\} \quad . \quad . \quad . \quad . \quad (38).$$

76. *Coupling of Intersecting Axes—Hooke's Universal Joint.*—Intersecting axes are coupled by a contrivance of Hooke's, known as the "universal joint," which belongs to the class of linkwork (see fig 25). Let O be the point of intersection of the axes $OC_1$, $OC_2$, and $\theta$ their angle of inclination to each other. The pair of shafts $C_1$, $C_2$ terminate in a pair of forks $F_1$, $F_2$, in bearings at the extremi-

ties of which turn the gudgeons at the ends of the arms of a rectangular cross, having its centre at O. This cross is the link; the connected points are the centres of the bearings $F_1$, $F_2$. At each instant each of those points moves at right angles to the central plane of its shaft and fork; therefore the line of intersection of the central planes of the two forks at any instant is the instantaneous axis of the cross, and the *velocity ratio* of the points $F_1$, $F_2$ (which, as the forks are equal, is also the *angular velocity ratio* of the shafts) is equal to the ratio of the distances of those points from that instantaneous axis. The *mean* value of that velocity ratio is that of equality, for each successive *quarter-turn* is made by both shafts in the same time; but its actual value fluctuates between the limits—

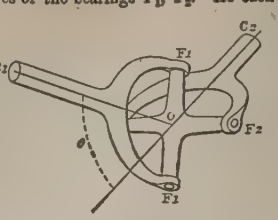

Fig. 25.

$$\left.\begin{aligned} &\frac{\alpha_2}{\alpha_1} = \frac{1}{\cos\theta} \text{ when } F_1 \text{ is the plane } OC_1C_2 \\ \text{and } &\frac{\alpha_2}{\alpha_1} = \cos\theta \text{ when } F_2 \text{ is in that plane} \end{aligned}\right\} \quad . \quad . \quad . \quad (89).$$

Its value at intermediate instants is given by the following equations:—let $\phi_1$, $\phi_2$ be the angles respectively made by the central planes of the forks and shafts with the plane $OC_1C_2$ at a given instant; then

$$\left.\begin{aligned} &\cos\theta = \tan\phi_1 \tan\phi_2 \\ \frac{\alpha_2}{\alpha_1} = -\frac{d\phi_2}{d\phi_1} &= \frac{\tan\phi_1 + \cot\phi_1}{\tan\phi_2 + \cot\phi_2} \end{aligned}\right\} \quad . \quad . \quad . \quad . \quad (40).$$

77. *Intermittent Linkwork—Click and Ratchet.*—A *click* acting upon a ratchet-wheel or rack, which it pushes or pulls through a certain arc at each forward stroke and leaves at rest at each backward stroke, is an example of intermittent linkwork. During the forward stroke the action of the click is governed by the principles of linkwork; during the backward stroke that action ceases. A *catch* or *pall*, turning on a fixed axis, prevents the ratchet-wheel or rack from reversing its motion.

### *Division 5. Trains of Mechanism.*

78. *General Principles.*—A *train of mechanism* consists of a series of pieces each of which is follower to that which drives it and driver to that which follows it.

The comparative motion of the first driver and last follower is obtained by combining the proportions expressing by their terms the velocity ratios and by their signs the directional relations of the several elementary combinations of which the train consists.

79. *Trains of Wheelwork.*—Let $A_1$, $A_2$, $A_3$, &c., $A_{m-1}$, $A_m$ denote a series of axes, and $a_1$, $a_2$, $a_3$, &c., $a_{m-1}$, $a_m$ their angular velocities. Let the axis $A_1$ carry a wheel of $N_1$ teeth, driving a wheel of $n_2$ teeth on the axis $A_2$, which carries also a wheel of $N_2$ teeth, driving a wheel of $n_3$ teeth on the axis $A_3$, and so on; the numbers of teeth in drivers being denoted by N's, and in followers by *n*'s, and the axes to which the wheels are fixed being denoted by numbers. Then the resulting velocity ratio is denoted by

$$\frac{a_m}{a_1} = \frac{a_2}{a_1} \cdot \frac{a_3}{a_2} \cdot \text{ &c. . . } \frac{a_m}{a_{m-1}} = \frac{N_1 \cdot N_2 \cdot \text{ &c. . . . } N_{m-1}}{n_2 \cdot n_3 \cdot \text{ &c. . . . } n_m} \quad (41);$$

that is to say, the velocity ratio of the last and first axes is the ratio of the product of the numbers of teeth in the drivers to the product of the numbers of teeth in the followers.

Supposing all the wheels to be in outside gearing, then, as each elementary combination reverses the direction of rotation, and as the number of elementary combinations $m-1$ is one less than the number of axes $m$, it is evident that if $m$ is odd the direction of rotation is preserved, and if even reversed.

It is often a question of importance to determine the number of teeth in a train of wheels best suited for giving a determinate velocity ratio to two axes. It was shown by Young that, to do this with the *least total number of teeth*, the velocity ratio of each elementary combination should approximate as nearly as possible to 3·59. This would in many cases give too many axes; and, as a useful practical rule, it may be laid down that from 3 to 6 ought to be the limit of the velocity ratio of an elementary combination in wheelwork. The smallest number of teeth in a pinion for epicycloidal teeth ought to be *twelve* (see sect. 59),—but it is better, for smoothness of motion, not to go below *fifteen*; and for involute teeth the smallest number is about *twenty-four*.

Let $\frac{B}{C}$ be the velocity ratio required, reduced to its least terms, and let B be greater than C. If $\frac{B}{C}$ is not greater than 6, and C lies between the prescribed minimum number of teeth (which may be called *t*) and its double $2t$, then one pair of wheels will answer the purpose, and B and C will themselves be the numbers required. Should B and C be inconveniently large, they are, if possible, to be resolved into factors, and those factors (or if they are too small, multiples of them) used for the number of teeth. Should B or C, or both, be at once inconveniently large and prime, then, instead of the exact ratio $\frac{B}{C}$, some ratio approximating to that ratio, and capable of resolution into convenient factors, is to be found by the method of continued fractions.

Should $\frac{B}{C}$ be greater than 6, the best number of elementary combinations $m-1$ will lie between

$$\frac{\log B - \log C}{\log 6} \text{ and } \frac{\log B - \log C}{\log 3}.$$

Then, if possible, B and C themselves are to be resolved each into $m-1$ factors (counting 1 as a factor), which factors, or multiples of them, shall be not less than *t* nor greater than $6t$; or if B and C contain inconveniently-large prime factors, an approximate velocity ratio, found by the method of continued fractions, is to be substituted for $\frac{B}{C}$ as before.

So far as the resultant velocity ratio is concerned, the *order* of the drivers N and of the followers *n* is immaterial; but to secure equable wear of the teeth, as explained in sect. 54, the wheels ought to be so arranged that, for each elementary combination, the greatest common divisor of N and *n* shall be either 1, or as small as possible.

80. *Double Hooke's Coupling.*—It has been shown in section 76 that the velocity ratio of a pair of shafts coupled by a universal joint fluctuates between the limits $\cos\theta$ and $\frac{1}{\cos\theta}$. Hence one or both of the shafts must have a vibratory and unsteady motion, injurious to the mechanism and framework. To obviate this evil a short intermediate shaft is introduced, making equal angles with the first and last shaft, coupled with each of them by a Hooke's joint, and having its own two forks in the same plane. Let $\alpha_1$, $\alpha_2$, $\alpha_3$ be the angular velocities of the first, intermediate, and last shaft in this *train of two Hooke's couplings*. Then, from the principles of sect. 76 it is evident that at each instant $\frac{\alpha_2}{\alpha_1} = \frac{\alpha_3}{\alpha_2}$, and consequently that $\alpha_3 = \alpha_1$; so that the fluctuations of angular velocity ratio caused by the first coupling are exactly neutralized by the second, and the first and last shafts have equal angular velocities at each instant.

81. *Converging and Diverging Trains of Mechanism.*—Two or more trains of mechanism may *converge* into one,—as when the two pistons of a pair of steam-engines, each through its own connecting-rod, act upon one crank-shaft. One train of mechanism may *diverge* into two or more,—as when a single shaft, driven by a prime mover, carries several pulleys, each of which drives a different machine. The principles of comparative motion in such converging and diverging trains are the same as in simple trains.

### *Division 6. Aggregate Combinations.*

82. *General Principles.*—Willis has designated as "aggregate combinations" those assemblages of pieces of mechanism in which the motion of one follower is the *resultant* of component motions impressed on it by more than one driver. Two classes of aggregate combinations may be distinguished which, though not different in their actual nature, differ in the *data* which they present to the designer, and in the method of solution to be followed in questions respecting them.

Class I. comprises those cases in which a piece A is not carried directly by the frame C, but by another piece B, *relatively* to which the motion of A is given,—the motion of the piece B relatively to the frame C being also given. Then the motion of A relatively to the frame C is the *resultant* of the motion of A relatively to B and of B relatively to C; and that resultant is to be found by the principles already explained in division 3 of this chapter, sects. 34 to 41.

Class II. comprises those cases in which the motions of three points in one follower are determined by their connexions with two or with three different drivers, so that the motion of the follower, as a whole, is to be determined by the principles of §§ 71, 78, pp. 690, 692.

This classification is founded on the kinds of problems arising from the combinations. Willis adopts another classification, founded on the *objects* of the combinations, which objects he divides into two classes, viz., (1) to produce *aggregate velocity*, or a velocity which is the resultant of two or more components in the same path, and (2) to produce *an aggregate path*, that is, to make a given point in a rigid body move in an assigned path by communicating certain motions to other points in that body.

It is seldom that one of these effects is produced without at the same time producing the other; but the classification of Willis

depends upon which of those two effects, even supposing them to occur together, is the practical object of the mechanism.

83. *Reduplication of Cords—Differential Windlass—Blocks, Sheaves, and Tackle.*—The axis C (fig. 26) carries a larger barrel AE and a smaller barrel DB, rotating as one piece with the angular velocity $a_1$ in the direction AE. The pulley or *sheave* FG has a weight W hung to its centre. A cord has one end made fast to and wrapped round the barrel AE; it passes from A under the sheave FG, and has the other end wrapped round and made fast to the barrel BD. Required the relation between the velocity of translation $v_2$ of W and the angular velocity $a_1$ of the *differential barrel*.

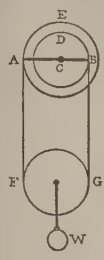

Fig. 26.

In this case $v_2$ is an *aggregate velocity*, produced by the joint action of the two drivers AE and BD, transmitted by wrapping connectors to FG, and combined by that sheave so as to act on the follower W, whose motion is the same with that of the centre of FG.

The velocity of the point F is $a_1 . AC$, *upward* motion being considered positive. The velocity of the point G is $-a_1 . CB$, *downward* motion being negative. Hence (p. 690, §§ 71, 72) the instantaneous axis of the sheave FG is in the diameter FG, at the distance

$$\frac{FG}{2} \cdot \frac{AC - BC}{AC + BC}$$

from the centre towards G; the angular velocity of the sheave is

$$a_2 = a_1 \cdot \frac{AC + BC}{FG};$$

and, consequently, the velocity of its centre is

$$v_2 = a_2 \cdot \frac{FG}{2} \cdot \frac{AC - BC}{AC + BC} = \frac{a_1(AC - BC)}{2} \quad . \quad . \quad (42),$$

or the *mean between the velocities of the two vertical parts of the cord*.

If the cord be fixed to the frame-work at the point B, instead of being wound on a barrel, the velocity of W is half that of AF.

A case containing several sheaves is called a *block*. A *fall-block* is attached to a fixed point; a *running-block* is movable to and from a fall-block, with which it is connected by two or more plies of a rope. The whole combination constitutes a *tackle* or *purchase*.

The two plies of a rope at opposite sides of a sheave in the fall-block have equal and opposite velocities. The two plies at opposite sides of a sheave in the running-block have velocities (as in the case of the sheave FG) differing equally in opposite directions from the velocity of the running-block.

One end of the rope is fastened either to the fall-block or the running-block. The other, or free end, is called the *fall*. Let $v_1$ be the velocity of the fall, $v_2$ that of the running-block; and let it be required to find their ratio; and let velocities towards the fall-block be positive, and from it negative.

CASE 1. If the fastened end of the rope be attached to the fall-block its velocity is 0, and this also is the velocity of the first ply. The rope passes under a sheave in the running-block, so that the velocity of the second ply is $2v_2$. It then passes over a sheave in the fall-block; the velocity of the third ply is $-2v_2$; then under a sheave in the running-block; the velocity of the fourth ply is $4v_2$; and so on,—the general law being this:—let $n$ be an *even* number, then

$$\left.\begin{array}{l} \text{the velocity of the } n^{\text{th}} \text{ ply} = nv_2 \\ \quad\quad\quad\quad (n+1)^{\text{th}} \text{ ply} = -nv_2 \\ = v_1, \text{ if the fall be the } (n+1)^{\text{th}} \text{ ply} \end{array}\right\} \quad . \quad . \quad . \quad (43).$$

CASE 2. If the fastened end of the rope be attached to the running-block, the velocity of the first ply is $v_2$; of the second, $-v_2$; of the third, $3v_2$; of the fourth, $-3v_2$; and, generally, if $n$ be an *odd* number,

$$\left.\begin{array}{l} \text{velocity of the } n^{\text{th}} \text{ ply} = nv_2 \\ \quad\quad\quad\quad (n+1)^{\text{th}} \text{ ply} = -nv_2 \\ = v_1, \text{ if the fall be the } (n+1)^{\text{th}} \text{ ply} \end{array}\right\} \quad . \quad . \quad . \quad (44).$$

Generally,—

$$\frac{v_1}{v_2} = -n \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (45),$$

where $n$ is the *number of plies of rope by which the running-block hangs*.

The sheaves in a block are usually made all of the same diameter, and turn on a fixed pin, and they have, consequently, different angular velocities. But by making the diameter of each sheave proportional to the velocity, relatively to the block, of the ply of rope which it is to carry, the angular velocities of the sheaves in one block may be rendered equal, so that the sheaves may be made all in one piece, and may have journals turning in fixed bearings. This is called *White's tackle*, from the inventor.

For details and technical terms see SHIPBUILDING.

84. *Differential Screw.*—On the same axis let there be two screws of the respective pitches $p_1$ and $p_2$, made in one piece, and rotating with the angular velocity $a$. Let this piece be called B. Let the first screw turn in a fixed nut C, and the second in a sliding nut A. The velocity of advance of B relatively to C is (according to sect. 41) $ap_1$, and of A relatively to B (according to sect. 67) $-ap_2$; hence the velocity of A relatively to C is

$$a(p_1 - p_2) \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (46),$$

being the same with the velocity of advance of a screw of the pitch $p_1 - p_2$. This combination, called *Hunter's* or the *differential screw*, combines the strength of a large thread with the slowness of motion due to a small one.

85. *Epicyclic Trains.*—The term *epicyclic train* is used by Willis to denote a train of wheels carried by an arm, and having certain rotations relatively to that arm, which itself rotates. The arm may either be driven by the wheels or assist in driving them. The comparative motions of the wheels and of the arm, and the *aggregate paths* traced by points in the wheels, are determined by the principles of the composition of rotations, and of the description of rolling curves, explained in sects. 37 to 40.

86. *Link Motion.*—Let S (fig. 27) be the shaft of a steam-engine, O its axis, $E_f$ the *forward eccentric*, suitably placed for moving the slide-valve when the shaft rotates forwards, F its centre, OF its crank-arm, $C_f$ its rod, $E_b$ the *backward eccentric*, suitably placed for moving the slide-valve when the shaft rotates backwards, B its centre, OB its crank-arm, $C_b$ its rod. L is a long narrow box called the *link*, jointed at $T_f$ and $T_b$ to the eccentric rods; R is the valve-rod which works the slide-valve, jointed to P, a slider, which, by moving either L or R, or both, can be adjusted to any required posi-

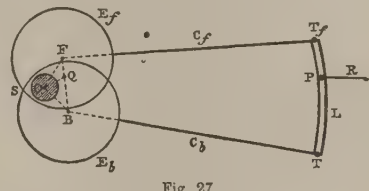

Fig. 27.

tion in the link. When P is at $T_f$ the valve is said to be in *full forward gearing*, being acted upon by $E_f$ alone. When P is at $T_b$ the valve is said to be in *full backward gearing*, being acted upon by $E_b$ alone. When P is placed in an intermediate position, the valve has an aggregate motion due to the joint action of $E_f$ and $E_b$. The most exact mode of determining that motion is to make a skeleton drawing of the apparatus in various positions; but an *approximation* to the motion of the valve may be obtained by joining FB, and taking Q so that

$$T_f P : T_b P :: FQ : BQ;$$

then the valve will move nearly as if it were worked by one eccentric, having its centre at Q.

87. *Parallel Motions (exact).*—A *parallel motion* is a combination of turning pieces in mechanism designed to guide the motion of a reciprocating piece either exactly or approximately in a straight line, so as to avoid the friction which arises from the use of straight guides for that purpose.

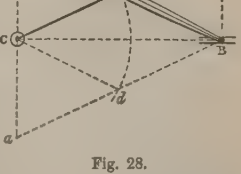

Fig. 28.

Fig. 28 represents an exact parallel motion, first proposed, it is believed, by Mr Scott Russell.

The arm CD turns on the axis C, and is jointed at D to the middle of the bar ADB, whose length is double of that of CD, and one of whose ends B is jointed to a slider, sliding in straight guides along the line CB. Draw BE perpendicular to CB, cutting CD produced in E, then E is the instantaneous axis of the bar ADB; and the direction of motion of A is at every instant perpendicular to EA, that is, along the straight line AC*a*. While the stroke of A is AC*a*, extending to equal distances on either side of C, and equal to twice the chord of the arc D*d*, the stroke of B is only equal to twice the sagitta; and thus A is guided through a comparatively long stroke by the sliding of B through a comparatively short stroke, and by rotatory motions at the joints C, D, B. (For details, see STEAM-ENGINE.)

88. *Parallel Motion—Watt's Approximate* (see fig. 29).—Let CT, *ct* be a pair of levers connected by a link T*t*, and oscillating about the axes Cc between the positions marked 1 and 3. Let the middle positions of the levers $CT_2$, $ct_2$ be parallel to each other. It is required to find a point P in the link T*t* such that its middle

position $P_2$ and its extreme positions $P_1$, $P_3$ shall be in the same straight line SS, perpendicular to $CT_2$, $ct_2$, and so to place the axes C, $c$ on the lines $CT_2$, $ct_2$ that the path of P between the positions $P_1$, $P_2$, $P_3$ shall be as near as possible to a straight line.

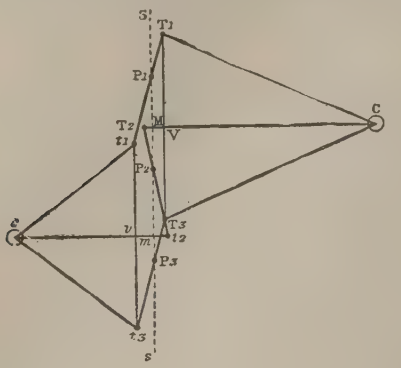

Fig. 29.

The axes C, $c$ are to be so placed that the middle M of the versed sine $VT_2$, and the middle $m$ of the versed sine $vt_2$, of the respective arcs whose equal chords $T_1T_3$, $t_1t_3$ represent the stroke, may each be in the line SS. Then $T_1$ and $T_3$ will be as far to one side of SS as $T_2$ is to the other, and $t_1$ and $t_3$ will be as far to the latter side of SS as $t_2$ is to the former; consequently, the two extreme positions of the links $T_1t_1$, $T_3t_3$ are parallel to each other, and inclined to SS at the same angle in one direction that the middle position of the link $T_2t_2$ is inclined to that line in the other direction, and the three intersections $P_1$, $P_2$, $P_3$ are at the same point on the link.

The position of the point P on the link is found by the following proportional equation:—

$$\left.\begin{array}{l} Tt : PT : Pt \\ :: TV + tv : TV : tv \\ :: CM + cm : cm : CM \end{array}\right\} \quad . \quad . \quad . \quad . \quad . \quad (47).$$

Suppose the axes C, $c$ to be given, the line of stroke SS, and the length of stroke $L = T_1T_3 = t_1t_3$, and that it is required to find the dimensions of the levers and link. Let fall CM and $cm$ perpendicular to SS; then

$$\left.\begin{array}{l} TV = \dfrac{L^2}{8CM}\,; \; tv = \dfrac{L^2}{8cm}\,; \\ CT = CM + \frac{1}{2}TV; \; ct = cm + \frac{1}{2}tv; \\ Tt = \sqrt{\{M n^2 + \frac{1}{4}(TV + tv)^2\}} \end{array}\right\} \quad . \quad . \quad . \quad (48).$$

If C and $c$ are at the same side of SS, the smaller of the two perpendiculars is to be treated as negative in the formulæ, and the difference of the versed sines used instead of their sum; and the point P will lie in the *prolongation* of the link beyond $Tt$ to the side of the longer lever. When the arcs of oscillation of the levers on either side of their middle positions do not exceed 20°, the intermediate portions of the path of P between $P_1$, $P_2$, and $P_3$ are near enough to a straight line for practical purposes; and that point may be used to guide a sliding piece, such as the piston-rod of a steam-engine, for which purpose this parallel motion was originally invented by Watt.

## CHAPTER II. ON APPLIED DYNAMICS.

89. *Laws of Motion.*—The action of a machine in transmitting *force* and *motion* simultaneously, or performing *work*, is governed, in common with the phenomena of moving bodies in general, by two "laws of motion," for which see pp. 676 *sq.*

90. *Comparison of Deviating Force with Gravity.*—See pp. 698, 699, §§ 104–106.

91. *Deviating Forces Classed—Deflecting Force—Accelerating and Retarding Forces.*—See p. 701, §§ 114–119

92. *Division of the Subject.*—On this classification of the deviating forces in machines is founded the following division of the subject of dynamics as applied to machines:—

*Division* 1.—Balanced forces in machines of uniform velocity.

*Division* 2.—Deflecting forces in such machines.

*Division* 3.—Working of machines of varying velocity.

### *Division* 1. *Balanced Forces in Machines of Uniform Velocity.*

93. *Application of Force to Mechanism.*—Forces are applied in units of weight; and the unit most commonly employed in Britain is the *pound avoirdupois*. The action of a force applied to a body is always in reality distributed over some definite space, either a volume of three dimensions or a surface of two. An example of a force distributed throughout a volume is the *weight* of the body itself, which acts on every particle, however small. The *pressure* exerted between two bodies at their surface of contact, or between the two parts of one body on either side of an ideal surface of separation, is an example of a force distributed over a surface. The mode of distribution of a force applied to a solid body requires to be considered when its stiffness and strength are treated of; but, in questions respecting the action of a force upon a rigid body considered as a whole, the *resultant* of the distributed force, determined according to the principles of statics, and considered as acting in a *single line* and applied at a *single point*, may, for the occasion, be substituted for the force as really distributed. Thus, the weight of each separate piece in a machine is treated as acting wholly at its *centre of gravity*, and each pressure applied to it as acting at a point called the *centre of pressure* of the surface to which the pressure is really applied.

94. *Forces applied to Mechanism Classed.*—If $\theta$ be the *obliquity* of a force F applied to a piece of a machine,—that is, the angle made by the direction of the force with the direction of motion of its point of application,—then by the principles of Statics, F may be resolved into two rectangular components, viz.:—

$$\left.\begin{array}{l} \text{Along the direction of motion, } P = F\cos\theta \\ \text{Across the direction of motion, } Q = F\sin\theta \end{array}\right\} \quad . \quad . \quad (49).$$

If the component along the direction of motion acts *with* the motion, it is called an *effort*; if *against* the motion, a *resistance*. The component *across* the direction of motion is a *lateral pressure*; the unbalanced lateral pressure on any piece, or part of a piece, is *deflecting force*. A lateral pressure may increase resistance by causing friction; the friction so caused acts against the motion, and is a resistance, but the lateral pressure causing it is not a resistance. Resistances are distinguished into *useful* and *prejudicial*, according as they arise from the useful effect produced by the machine or from other causes.

95. *Work.*—*Work* consists in moving against resistance. The work is said to be *performed*, and the resistance *overcome*. Work is measured by the product of the resistance into the distance through which its point of application is moved. The *unit of work* commonly used in Britain is a resistance of one pound overcome through a distance of one foot, and is called a *foot-pound*.

Work is distinguished into *useful work* and *prejudicial* or *lost work*, according as it is performed in producing the useful effect or the machine, or in overcoming prejudicial resistance.

96. *Energy—Potential Energy.*—*Energy* means *capacity for performing work*. The *energy of an effort*, or *potential energy*, is measured by the product of the effort into the distance through which its point of application is *capable* of being moved. The unit of energy is the same with the unit of work.

When the point of application of an effort *has been moved* through a given distance, energy is said to have been *exerted* to an amount expressed by the product of the effort into the distance through which its point of application has been moved.

97. *Variable Effort and Resistance.*—If an effort has different magnitudes during different portions of the motion of its point of application through a given distance, let each different magnitude of the effort P be multiplied by the length $\Delta s$ of the corresponding portion of the path of the point of application; the sum

$$\Sigma . P\Delta s \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (50)$$

is the whole energy exerted. If the effort varies by insensible gradations, the energy exerted is the integral or limit towards which that sum approaches continually as the divisions of the path are made smaller and more numerous, and is expressed by

$$\int P ds \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (51).$$

Similar processes are applicable to the finding of the work performed in overcoming a varying resistance.

98. *Dynamometer or Indicator.*—A dynamometer or indicator is an instrument which measures and records the energy exerted by an effort. It usually consists essentially, first, of a piece of paper moving with a velocity proportional to that of the point of application of the effort, and having a straight line marked on it parallel to its direction of motion, called the zero line; and, secondly, of a spring acted upon and bent by the effort, and carrying a pencil whose perpendicular distance from the zero line, as regulated by the bending of the spring, is proportional to the effort. The pencil traces on the piece of paper a line such that its *ordinate* perpendicular to the zero line at a given point represents the effort P for the corresponding point in the path of the point of effort, and the *area between two ordinates* represents the energy exerted, $\int P ds$, for the corresponding portion of the path of the point of effort.

99. *Principle of the Equality of Energy and Work.*—From the first law of motion it follows that in a machine whose pieces move with uniform velocities the efforts and resistances must balance each

other. Now from the laws of statics (see above) it is known that, in order that a system of forces applied to a system of connected points may be in equilibrium, it is necessary that the sum formed by putting together the products of the forces by the respective distances through which their points of application are capable of moving simultaneously, each along the direction of the force applied to it, shall be zero,—products being considered positive or negative according as the direction of the forces and the possible motions of their points of application are the same or opposite.

In other words, the sum of the negative products is equal to the sum of the positive products. This principle, applied to a machine whose parts move with uniform velocities, is equivalent to saying that in any given interval of time *the energy exerted is equal to the work performed.*

The symbolical expression of this law is as follows:—let efforts be applied to one or any number of points of a machine; let any one of these efforts be represented by P, and the distance traversed by its point of application in a given interval of time by $ds$; let resistances be overcome at one or any number of points of the same machine; let any one of these resistances be denoted by R, and the distance traversed by its point of application in the given interval of time by $ds'$; then

$$\Sigma.Pds = \Sigma.Rds' \quad . \quad . \quad . \quad . \quad . \quad . \quad (52).$$

The lengths $ds$, $ds'$ are proportional to the velocities of the points to whose paths they belong, and the proportions of those velocities to each other are deducible from the construction of the machine by the principles of pure mechanism explained in Chapter I.

100. *Efficiency.*—The *efficiency* of a machine is the ratio of the *useful* work to the *total* work,—that is, to the energy exerted,—and is represented by

$$\frac{\Sigma.R_u ds'}{\Sigma.Rds'} = \frac{\Sigma.R_u ds'}{\Sigma.R_u ds' + \Sigma.R_p ds'} = \frac{\Sigma.R_u ds'}{\Sigma.Pds} = \frac{U}{E} \quad . \quad . \quad (53),$$

$R_u$ being taken to represent useful and $R_p$ prejudicial resistances.

The more nearly the efficiency of a machine approaches to unity the better is the machine.

101. *Power and Effect.*—The *power* of a machine is the energy exerted, and the *effect* the useful work performed, in some interval of time of definite length, such as a second, an hour, or a day.

The unit of power, called conventionally a *horse-power*, is 550 foot-pounds per second, or 33,000 foot-pounds per minute, or 1,980,000 foot-pounds per hour.

102. *Modulus of a Machine.*—In the investigation of the properties of a machine, the useful resistances to be overcome and the useful work to be performed are usually given. The prejudicial resistances are generally functions of the useful resistances of the weights of the pieces of the mechanism, and of their form and arrangement; and, having been determined, they serve for the computation of the *lost* work, which, being added to the useful work, gives the expenditure of energy required. The result of this investigation, expressed in the form of an equation between this energy and the useful work, is called by Moseley the *modulus* of the machine. The general form of the modulus may be expressed thus—

$$E = U + \phi(U, A) + \psi(A) \quad . \quad . \quad . \quad . \quad . \quad (54),$$

where A denotes some quantity or set of quantities depending on the form, arrangement, weight, and other properties of the mechanism. Moseley, however, has pointed out that in most cases this equation takes the much more simple form of

$$E = (1 + A)U + B, \quad . \quad . \quad . \quad . \quad . \quad . \quad (55),$$

where A and B are *constants*, depending on the form, arrangement, and weight of the mechanism. The efficiency corresponding to the last equation is

$$\frac{U}{E} = \frac{1}{1 + A + B/U} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (56).$$

103. *Trains of Mechanism.*—In applying the preceding principles to a train of mechanism, it may either be treated as a whole, or it may be considered in sections consisting of single pieces, or of any convenient portion of the train,—each section being treated as a machine driven by the effort applied to it and energy exerted upon it through its line of connexion with the preceding section, performing useful work by driving the following section, and losing work by overcoming its own prejudicial resistances.

It is evident that *the efficiency of the whole train is the product of the efficiencies of its sections.*

104. *Rotating Pieces—Couples of Forces.*—It is often convenient to express the energy exerted upon and the work performed by a turning piece in a machine in terms of the *moment* of the *couples of forces* acting on it, and of the angular velocity. See p. 728, § 219.

The ordinary British unit of moment is a *foot-pound*; but it is to be remembered that this is a foot-pound of a different sort from the unit of energy and work.

If a force be applied to a turning piece in a line not passing through its axis, the axis will press against its bearings with an equal and parallel force, and the equal and opposite reaction of the bearings will constitute, together with the first-mentioned force, a couple whose arm is the perpendicular distance from the axis to the line of action of the first force.

A couple is said to be *right* or *left handed* with reference to the observer, according to the direction in which it tends to turn the body, and is a *driving* couple or a *resisting* couple according as its tendency is with or against that of the actual rotation.

Let $dt$ be an interval of time, $a$ the angular velocity of the piece; then $adt$ is the angle through which it turns in the interval $dt$, and $ds = vdt = radt$ is the distance through which the point of application of the force moves. Let P represent an effort, so that $Pr$ is a driving couple, then

$$Pds = Pvdt = Pradt = Madt \quad . \quad . \quad . \quad . \quad . \quad (57)$$

is the energy exerted by the couple M in the interval $dt$; and a similar equation gives the work performed in overcoming a resisting couple. When several couples act on one piece, the resultant of their moments is to be multiplied by the common angular velocity of the whole piece.

105. *Reduction of Forces to a given Point, and of Couples to the Axis of a given Piece.*—In computations respecting machines it is often convenient to substitute for a force applied to a given point or a couple applied to a given piece, the *equivalent* force or couple applied to some other point or piece; that is to say, the force or couple, which, if applied to the other point or piece, would exert equal energy or employ equal work. The principles of this reduction are that the ratio of the given to the equivalent force is the reciprocal of the ratio of the velocities of their points of application, and the ratio of the given to the equivalent couple is the reciprocal of the ratio of the angular velocities of the pieces to which they are applied.

These velocity ratios are known by the construction of the mechanism, and are independent of the absolute speed.

106. *Balanced Lateral Pressure of Guides and Bearings.*—The most important part of the lateral pressure on a piece of mechanism is the reaction of its guides, if it is a sliding piece, or of the bearings of its axis, if it is a turning piece; and the balanced portion of this reaction is equal and opposite to the resultant of all the other forces applied to the piece, its own weight included. There may be or may not be an unbalanced component in this pressure, due to the deviated motion. Its laws will be considered in the sequel.

107. *Friction—Unguents.*—The most important kind of resistance in machines is the *friction* or *rubbing resistance* of surfaces which slide over each other. The *direction* of the resistance of friction is opposite to that in which the sliding takes place. Its *magnitude* is the product of the *normal pressure* or force which presses the rubbing surfaces together in a direction perpendicular to themselves into a specific constant already mentioned in Part I., sect. 13, as the *coefficient of friction*, which depends on the nature and condition of the surfaces of the unguent, if any, with which they are covered. The *total pressure* exerted between the rubbing surfaces is the resultant of the normal pressure and of the friction, and its *obliquity*, or inclination to the common perpendicular of the surfaces, is the *angle of repose* formerly mentioned in sect. 13, whose tangent is the coefficient of friction. Thus, let N be the normal pressure, R the friction, T the total pressure, $f$ the coefficient of friction, and $\phi$ the angle of repose; then

$$\left.\begin{aligned} f &= \tan\phi \quad . \quad . \quad . \\ R &= fN = N\tan\phi = T\sin\phi \end{aligned}\right\} \quad . \quad . \quad . \quad . \quad . \quad (58).$$

Experiments on friction have been made by Coulomb, Vince, Rennie, Wood, D. Rankine, and others. The most complete and elaborate experiments are those of Morin, published in his *Notions Fondamentales de Mécanique*, and republished in Britain in the works of Moseley and Gordon. The following is an exceedingly condensed abstract of the most important results, as regards machines, of these experiments:—

| Surfaces. | $f$. |
|---|---|
| Wood on wood, dry | 0·25 to 0·5 |
| Do., soaped | 0·2 |
| Metals on oak, dry | 0·5 to 0·6 |
| Do., wet | 0·24 to 0·26 |
| Do., soaped | 0·2 |
| Do., elm, dry | 0·2 to 0·25 |
| Hemp on oak, dry | 0·53 |
| Do., wet | 0·33 |
| Leather on oak, wet or dry | 0·27 to 0·35 |
| Leather on metals, dry | 0·56 |
| Do., wet | 0·36 |
| Do., greasy | 0·23 |
| Do., oiled | 0·15 |
| Metals on metals, dry | 0·15 to 0·2 |
| Do., wet | 0·30 |
| Smooth surfaces with ungents, occasionally greased | 0·07 to 0·08 |
| Do. do., well greased | 0·05 |
| Do. do., do., best results | 0·03 to 0·036 |

It is to be understood that the above-stated law of friction is only true for dry surfaces when the pressure is not sufficient to indent or abrade the surfaces, and for greased surfaces when the pressure is not sufficient to force out the unguent from between the surfaces. If the proper limit be exceeded, the friction increases more rapidly than in the simple ratio of the normal pressure.

The limit of pressure for unguents diminishes as the speed increases. The following are some of its approximate values as inferred from experience in railway locomotive and carriage axles:—

| | | | |
|---|---|---|---|
| Velocity of rubbing in feet per second | 1 | 2½ | 5 |
| Intensity of normal pressure per lb per square inch of surface | 392 | 224 | 140 |

In pivots, the intensity of the pressure is usually fixed at about one ton per square inch.

Unguents should be comparatively thick for heavy pressures, that they may resist being forced out, and comparatively thin for light pressures, that their viscidity may not add to the resistance.

Unguents are of three classes, viz.:—

1. *Fatty*: consisting of animal or vegetable fixed oils, such as tallow, lard, lard-oil, seal-oil, whale-oil, olive-oil. *Drying* oils, which absorb oxygen and harden, are obviously unfit for unguents.

2. *Soapy*: composed of fatty oil, alkali, and water. The best grease of this class should not contain more than about 25 or 30 per cent. of water; bad kinds contain 40 or 50 per cent. The additional water diminishes the cost, but spoils the unguent.

3. *Bituminous*: composed of solid and liquid mineral compounds of hydrogen and carbon.

108. *Work of Friction—Moment of Friction.*—The work performed in a unit of time in overcoming the friction of a pair of surfaces is the product of the friction by the velocity of sliding of the surfaces over each other, if that is the same throughout the whole extent of the rubbing surfaces. If that velocity is different for different portions of the rubbing surfaces, the velocity of each portion is to be multiplied by the friction of that portion, and the results summed or integrated.

When the relative motion of the rubbing surfaces is one of rotation, the work of friction in a unit of time, for a portion of the rubbing surfaces at a given distance from the axis of rotation, may be found by multiplying together the friction of that portion, its distance from the axis, and the angular velocity. The product of the force of friction by the distance at which it acts from the axis of rotation is called the *moment of friction*. The total moment of friction of a pair of rotating rubbing surfaces is the sum or integral of the moments of friction of their several portions.

To express this symbolically, let $du$ represent the area of a portion of a pair of rubbing surfaces at a distance $r$ from the axis of their relative rotation; $p$ the intensity of the normal pressure at $du$ per unit of area; and $f$ the coefficient of friction. Then the moment of friction of $du$ is

$$fprdu;$$

the total moment of friction is

$$f\int pr.du;$$

and the work performed in a unit of time in overcoming friction, when the angular velocity is $a$, is

$$af\int pr.du. \quad \ldots\ldots\ldots \quad (59).$$

It is evident that the moment of friction, and the work lost by being performed in overcoming friction, are less in a rotating piece as the bearings are of smaller radius. But a limit is put to the diminution of the radii of journals and pivots by the conditions of durability and of proper lubrication stated in sect. 107, and also by conditions of strength and stiffness.

109. *Total Pressure between Journal and Bearing.*—A single piece rotating with an uniform velocity has four mutually balanced forces applied to it:—(1) the effort exerted on it by the piece which drives it; (2) the resistance of the piece which follows it,—which may be considered for the purposes of the present question as useful resistance; (3) its weight; and (4) the reaction of its own cylindrical bearings. There are given the following data:—

The direction of the effort.
The direction of the useful resistance.
The weight of the piece and the direction in which it acts.
The magnitude of the useful resistance.
The radius of the bearing $r$.
The angle of repose $\phi$, corresponding to the friction of the journal on the bearing.

And there are required the following:—

The direction of the reaction of the bearing.
The magnitude of that reaction.
The magnitude of the effort.

Let the useful resistance and the weight of the piece be compounded by the principles of statics into one force, and let this be called *the given force*.

The directions of the effort and of the given force are either parallel or meet in a point. If they are parallel, the direction of the reaction of the bearing is also parallel to them; if they meet in a point, the direction of the reaction traverses the same point.

Also, let AAA, fig. 30, be a section of the bearing, and C its axis; then the direction of the reaction, at the point where it intersects the circle AAA, must make the angle $\phi$ with the radius of that circle; that is to say, it must be a line such as PT touching the smaller circle BB, whose radius is $r.\sin\phi$. The side on which it touches that circle is determined by the fact that the obliquity of the reaction is such as to oppose the rotation.

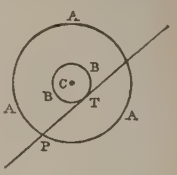

Fig. 30.

Thus is determined the direction of the reaction of the bearing; and the magnitude of that reaction and of the effort are then found by the principles of the equilibrium of three forces already stated in Part I., sect. 7 (see also p. 702, § 124).

The work lost in overcoming the friction of the bearing is the same with that which would be performed in overcoming at the circumference of the small circle BB a resistance equal to the whole pressure between the journal and bearing.

In order to diminish that pressure to the smallest possible amount, the effort, and the resultant of the useful resistance, and the weight of the piece (called above the "given force") ought to be opposed to each other as directly as is practicable consistently with the purposes of the machine.

110. *Friction of Pivots and Collars.*—When a shaft is acted upon by a force tending to shift it lengthways, that force must be balanced by the reaction of a bearing against a *pivot* at the end of the shaft; or, if that be impossible, against one or more *collars*, or rings *projecting* from the body of the shaft. The bearing of the pivot is called a *step* or *footstep*. Pivots require great hardness, and are usually made of steel. The *flat* pivot is a cylinder of steel having a plane circular end as a rubbing surface. Let N be the total pressure sustained by a flat pivot of the radius $r$; if that pressure be uniformly distributed, which is the case when the rubbing surfaces of the pivot and its step are both true planes, the *intensity* of the pressure is

$$p = \frac{N}{\pi r^2} \quad \ldots\ldots\ldots \quad (60);$$

and, introducing this value into equation 59, the *moment of friction of the flat pivot* is found to be

$$\tfrac{2}{3}fNr \quad \ldots\ldots\ldots \quad (61),$$

or two-thirds of that of a cylindrical journal of the same radius under the same normal pressure.

The friction of a *conical* pivot exceeds that of a flat pivot of the same radius, and under the same pressure, in the proportion of the side of the cone to the radius of its base.

The moment of friction of a *collar* is given by the formula—

$$\tfrac{2}{3}fN\frac{r^3 - r'^3}{r^2 - r'^2} \quad \ldots\ldots\ldots \quad (62),$$

where $r$ is the external and $r'$ the internal radius.

In the *cup and ball* pivot the end of the shaft and the step present two recesses facing each other, into which are fitted two shallow cups of steel or hard bronze. Between the concave spherical surfaces of those cups is placed a steel ball, being either a complete sphere or a lens having convex surfaces of a somewhat less radius than the concave surfaces of the cups. The moment of friction of this pivot is at first almost inappreciable from the extreme smallness of the radius of the circles of contact of the ball and cups, but, as they wear, that radius and the moment of friction increase.

It appears that the rapidity with which a rubbing surface wears away is proportional to the friction and to the velocity jointly, or nearly so. Hence the pivots already mentioned wear unequally at different points, and tend to alter their figures. Schiele has invented a pivot which preserves its original figure by wearing equally at all points in a direction parallel to its axis. The following are the principles on which this equality of wear depends:—

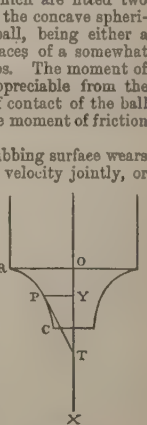

Fig 31.

The rapidity of wear of a surface measured in an *oblique* direction is to the rapidity of wear measured normally as the secant of the obliquity is to unity. Let OX (fig. 31) be the axis of a pivot, and let RPC be a portion of a curve such that at any point P the secant of the obliquity to the normal of the curve of a line parallel to the axis is inversely proportional to the ordinate PY, to which the velocity of P is proportional. The rotation of that curve round OX will generate the form of pivot required. Now let PT be a tangent to the

curve at P, cutting OX in T; PT = PY × *secant obliquity*, and this is to be a constant quantity; hence the curve is that known as the *tractory* of the straight line OX, in which PT = OR = constant. This curve is described by having a fixed straight edge parallel to OX, along which slides a slider carrying a pin whose centre is T. On that pin turns an arm, carrying at a point P a tracing-point, pencil, or pen. Should the pen have a nib of two jaws, like those of an ordinary drawing-pen, the plane of the jaws must pass through PT. Then, while T is slid along the axis from O towards X, P will be drawn after it from R towards C along the tractory. This curve, being an asymptote to its axis, is capable of being indefinitely prolonged towards X; but in designing pivots it should stop before the angle PTY becomes less than the angle of repose of the rubbing surfaces, otherwise the pivot will be liable to stick in its bearing.

The moment of friction of "Schiele's anti-friction pivot," as it is called, is equal to that of a cylindrical journal of the radius OR = PT the constant tangent, under the same pressure.

111. *Friction of Teeth.*—Let N be the normal pressure exerted between a pair of teeth of a pair of wheels; $s$ the total distance through which they slide upon each other; $n$ the number of pairs of teeth which pass the plane of axis in a unit of time; then

$$nfNs \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (63)$$

is the work lost in unity of time by the friction of the teeth. The sliding $s$ is composed of two parts, which take place during the approach and recess respectively. Let those be denoted by $s_1$ and $s_2$, so that $s = s_1 + s_2$. In sect. 55 the *velocity* of sliding at any instant has been given, viz., $u = c(\alpha_1 + \alpha_2)$, where $u$ is that velocity, $c$ the distance TI at any instant from the point of contact of the teeth to the pitch-point, and $\alpha_1$, $\alpha_2$ the respective angular velocities of the wheels.

Let $v$ be the common velocity of the two pitch-circles, $r_1$, $r_2$ their radii; then the above equation becomes

$$u = cv\left(\frac{1}{r_1} + \frac{1}{r_2}\right).$$

To apply this to involute teeth, let $c_1$ be the length of the approach, $c_2$ that of the recess, $u_1$ the *mean* velocity of sliding during the approach, $u_2$ that during the recess; then

$$u_1 = \frac{c_1 v}{2}\left(\frac{1}{r_1} + \frac{1}{r_2}\right); \; u_2 = \frac{c_2 v}{2}\left(\frac{1}{r_1} + \frac{1}{r_2}\right)$$

also, let $\theta$ be the obliquity of the action; then the times occupied by the approach and recess are respectively

$$\frac{c_1}{v\cos\theta}, \qquad \frac{c_2}{v\cos\theta};$$

giving, finally, for the length of sliding between each pair of teeth,

$$s = s_1 + s_2 = \frac{c_1^2 + c_2^2}{2\cos\theta}\left(\frac{1}{r_1} + \frac{1}{r_2}\right) \quad . \quad . \quad . \quad . \quad (64),$$

which, substituted in equation 63, gives the work lost in a unit of time by the friction of involute teeth. This result, which is exact for involute teeth, is approximately true for teeth of any figure.

For inside gearing, if $r_1$ be the less radius and $r_2$ the greater, $\frac{1}{r_1} - \frac{1}{r_2}$ is to be substituted for $\frac{1}{r_1} + \frac{1}{r_2}$.

112. *Friction of Cords and Belts.*—A flexible band, such as a cord, rope, belt, or strap, may be used either to exert an effort or a resistance upon a pulley round which it wraps. In either case the tangential force, whether effort or resistance, exerted between the band and the pulley is their mutual friction, caused by and proportional to the normal pressure between them.

Let $T_1$ be the tension of the free part of the band at that side *towards* which it tends to draw the pulley, or *from* which the pulley tends to draw it; $T_2$ the tension of the free part at the other side; T the tension of the band at any intermediate point of its arc of contact with the pulley; $\theta$ the ratio of the length of that arc to the radius of the pulley; $d\theta$ the ratio of an indefinitely small element of that arc to the radius; $F = T_1 - T_2$ the total friction between the band and the pulley; $dF$ the elementary portion of that friction due to the elementary arc $d\theta$; $f$ the coefficient of friction between the materials of the band and pulley.

Then, according to a well-known principle in statics, the normal pressure at the elementary arc $d\theta$ is $T d\theta$, T being the mean tension of the band at that elementary arc; consequently the friction on that arc is $dF = fT d\theta$. Now that friction is also the difference between the tensions of the band at the two ends of the elementary arc, or $dT = dF = fT d\theta$; which equation, being integrated throughout the entire arc of contact, gives the following formulæ:—

$$\left.\begin{aligned} &\text{hyp. log}\frac{T_1}{T_2} = f\theta \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \\ &\frac{T_1}{T_2} = e^{f\theta} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \\ &F = T_1 - T_2 = T_1(1 - e^{-f\theta}) = T_2(e^{f\theta} - 1) \end{aligned}\right\} \quad . \quad . \quad (65).$$

When a belt connecting a pair of pulleys has the tensions of its two sides originally equal, the pulleys being at rest, and when the pulleys are next set in motion, so that one of them drives the other by means of the belt, it is found that the advancing side of the belt is exactly as much tightened as the returning side is slackened, so that the *mean* tension remains unchanged. Its value is given by this formula—

$$\frac{T_1 + T_2}{2} = \frac{e^{f\theta} + 1}{2(e^{f\theta} - 1)} \quad . \quad . \quad . \quad . \quad . \quad (66),$$

which is useful in determining the original tension required to enable a belt to transmit a given force between two pulleys.

The equations 65 and 66 are applicable to a kind of *brake* called a *friction-strap*, used to stop or moderate the velocity of machines by being tightened round a pulley. The strap is usually of iron, and the pulley of hard wood.

Let $a$ denote the arc of contact expressed in *turns and fractions of a turn*; then

$$\left.\begin{aligned} &\theta = 6{\cdot}2832a \\ &e^{f\theta} = \text{number whose common logarithm is } 2{\cdot}7288fa \end{aligned}\right\} \quad (67).$$

113. *Stiffness of Ropes.*—Ropes offer a resistance to being bent, and, when bent, to being straightened again, which arises from the mutual friction of their fibres. It increases with the sectional area of the rope, and is inversely proportional to the radius of the curve into which it is bent.

The *work lost* in pulling a given length of rope over a pulley is found by multiplying the length of the rope in feet by its stiffness in pounds, that stiffness being the excess of the tension at the leading side of the rope above that at the following side, which is necessary to bend it into a curve fitting the pulley, and then to straighten it again.

The following empirical formulæ for the stiffness of hempen ropes have been deduced by Morin from the experiments of Coulomb:—

Let F be the stiffness in pounds avoirdupois; $d$ the diameter of the rope in inches, $n = 48d^2$ for white ropes and $35d^2$ for tarred ropes; $r$ the *effective* radius of the pulley in inches; T the tension in pounds. Then

$$\left.\begin{aligned} &\text{For white ropes, } F = \frac{n}{r}(0{\cdot}0012 + 0{\cdot}001026n + 0{\cdot}0012T) \\ &\text{For tarred ropes, } F = \frac{n}{r}(0{\cdot}006 + 0{\cdot}001392n + 0{\cdot}00168T). \end{aligned}\right\} \quad (68).$$

114. *Friction-Couplings.*—Friction is useful as a means of communicating motion where sudden changes either of force or velocity take place, because, being limited in amount, it may be so adjusted as to limit the forces which strain the pieces of the mechanism within the bounds of safety. Amongst contrivances for effecting this object are *friction-cones*. A rotating shaft carries upon a cylindrical portion of its figure a wheel or pulley turning loosely on it, and consequently capable of remaining at rest when the shaft is in motion. This pulley has fixed to one side, and concentric with it, a short frustum of a hollow cone. At a small distance from the pulley the shaft carries a short frustum of a solid cone accurately turned to fit the hollow cone. This frustum is made always to turn along with the shaft by being fitted on a square portion of it, or by means of a rib and groove, or otherwise, but is capable of a slight longitudinal motion, so as to be pressed into, or withdrawn from, the hollow cone by means of a lever. When the cones are pressed together or engaged, their friction causes the pulley to rotate along with the shaft; when they are disengaged, the pulley is free to stand still. The angle made by the sides of the cones with the axis should not be less than the angle of repose. In the *friction-clutch*, a pulley loose on a shaft has a hoop or gland made to embrace it more or less tightly by means of a screw; this hoop has short projecting arms or ears. A fork or *clutch* rotates along with the shaft, and is capable of being moved longitudinally by a handle. When the clutch is moved towards the hoop, its arms catch those of the hoop, and cause the hoop to rotate and to communicate its rotation to the pulley by friction. There are many other contrivances of the same class, but the two just mentioned may serve for examples.

115. *Heat of Friction—Unguents.*—The work lost in friction is employed in producing heat. This fact is very obvious, and has been known from a remote period; but the *exact* determination of the proportion of the work lost to the heat produced, and the experimental proof that that proportion is the same under all circumstances, and with all materials, solid, liquid, and gaseous, are comparatively recent achievements of Joule. The quantity of work which produces a British unit of heat (or so much heat as elevates the temperature of one pound of pure water, at or near ordinary atmospheric temperatures, by one degree of Fahrenheit) is 772 foot-pounds. This constant, now designated as "Joule's equivalent," is the principal experimental datum of the science of thermodynamics.

The heat produced by friction, when moderate in amount, is useful in softening and liquefying thick unguents; but when excessive it

is prejudicial, by decomposing the unguents, and sometimes even by softening the metal of the bearings, and raising their temperature so high as to set fire to neighbouring combustible matters.

Excessive heating is prevented by a constant and copious supply of a good unguent. The elevation of temperature produced by the friction of a journal is sometimes used as an experimental test of the quality of unguents. When the velocity of rubbing is about 4 or 5 feet per second, the elevation of temperature has been found by some recent experiments to be, with good fatty and soapy unguents, 40° to 50° Fahr.; with good mineral unguents, about 30°.

116. *Rolling Resistance.*—By the rolling of two surfaces over each other without sliding a resistance is caused which is called sometimes "rolling friction," but more correctly *rolling resistance*. It is of the nature of a *couple*, resisting rotation. Its *moment* is found by multiplying the normal pressure between the rolling surfaces by an *arm*, whose length depends on the nature of the rolling surfaces, and the work lost in a unit of time in overcoming it is the product of its moment by the *angular velocity* of the rolling surfaces relatively to each other. The following are approximate values of the arm in decimals of a foot:—

| | |
|---|---|
| Oak upon oak | 0·006 (Coulomb). |
| Lignum vitæ on oak | 0 001 ,, |
| Cast iron on cast iron | 0·002 (Tredgold). |

117. *Reciprocating Forces—Stored and Restored Energy.*—When a force acts on a machine alternately as an effort and as a resistance, it may be called a *reciprocating force*. Of this kind is the weight of any piece in the mechanism whose centre of gravity alternately rises and falls; for during the rise of the centre of gravity that weight acts as a resistance, and energy is employed in lifting it to an amount expressed by the product of the weight into the vertical height of its rise; and during the fall of the centre of gravity the weight acts as an effort, and exerts in assisting to perform the work of the machine an amount of energy exactly equal to that which had previously been employed in lifting it. Thus that amount of energy is not lost, but has its operation deferred; and it is said to be *stored* when the weight is lifted, and *restored* when it falls.

In a machine of which each piece is to move with a uniform velocity, if the effort and the resistance be constant, the weight of each piece must be balanced on its axis, so that it may produce lateral pressure only, and not act as a reciprocating force. But if the effort and the resistance be alternately in excess, the uniformity of speed may still be preserved by so adjusting some moving weight in the mechanism that when the effort is in excess it may be lifted, and so balance and employ the excess of effort, and that when the resistance is in excess it may fall, and so balance and overcome the excess of resistance,—thus *storing* the periodical excess of energy, and *restoring* that energy to perform the periodical excess of work.

Other forces besides gravity may be used as reciprocating forces for storing and restoring energy,—for example, the elasticity of a spring or of a mass of air.

In most of the delusive machines commonly called "perpetual motions," of which so many are patented in each year, and which are expected by their inventors to perform work without receiving energy, the fundamental fallacy consists in an expectation that some reciprocating force shall restore more energy than it has been the means of storing.

### *Division 2. Deflecting Forces.*

118. *Deflecting Force for Translation in a Curved Path.*—In machinery, deflecting force is supplied by the tenacity of some piece, such as a crank, which guides the deflected body in its curved path, and is *unbalanced*, being employed in producing deflexion, and not in balancing another force.

119. *Centrifugal Force.*—See p. 682, § 35, and p. 701, § 119.

120. *Rectangular Resolution of Centrifugal Force.*—See p. 701, §§ 117 and 119.

121. *Centrifugal Force of a Rotating Body.*—*The centrifugal force exerted by a rotating body on its axis of rotation is the same in magnitude as if the mass of the body were concentrated at its centre of gravity, and acts in a plane passing through the axis of rotation and the centre of gravity of the body.*

The particles of a rotating body exert centrifugal forces on each other, which strain the body, and tend to tear it asunder; but these forces balance each other, and do not affect the resultant centrifugal force exerted on the axis of rotation.[1]

*If the axis of rotation traverses the centre of gravity of the body, the centrifugal force exerted on that axis is nothing.*

Hence, unless there be some reason to the contrary, each piece of a machine should be balanced on its axis of rotation; otherwise the centrifugal force will cause strains, vibration, and increased friction, and a tendency of the shafts to jump out of their bearings.

122. *Centrifugal Couples of a Rotating Body.*—Besides the tendency (if any) of the combined centrifugal forces of the particles of a rotating body to *shift* the axis of rotation, they may also tend to *turn* it out of its original direction. The latter tendency is called a *centrifugal couple*, and vanishes for rotation about a principal axis (see p. 732, § 237).

It is essential to the steady motion of every rapidly rotating piece in a machine that its axis of rotation should not merely traverse its centre of gravity, but should be a permanent axis; for otherwise the centrifugal couples will increase friction, produce oscillation of the shaft, and tend to make it leave its bearings.

The principles of this and the preceding section are those which regulate the adjustment of the weight and position of the *counterpoises* which are placed between the spokes of the driving-wheels of locomotive engines.

123. *Revolving Pendulum—Governors.*—In fig. 32 AO represents an upright axis or spindle; B a weight called a *bob*, suspended by rod OB from a horizontal axis at O, carried by the vertical axis. When the spindle is at rest the bob hangs close to it; when the spindle rotates, the bob, being made to revolve round it, diverges until the resultant of the centrifugal force and the weight of the bob is a force acting at O in the direction OB, and then it revolves steadily in a circle. This combination is called a *revolving, centrifugal*, or *conical pendulum*. Revolving pendulums are usually constructed with *pairs* of rods and bobs, as OB, O*b*, hung at opposite sides of the spindle, that the centrifugal forces exerted at the point O may balance each other.

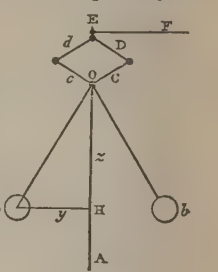

Fig. 32.

In finding the position in which the bob will revolve with a given angular velocity $\alpha$, for most practical cases connected with machinery the mass of the rod may be considered as insensible compared with that of the bob. Let the bob be a sphere, and from the centre of that sphere draw $BH = y$ perpendicular to OA. Let $OH = z$; let W be the weight of the bob, F its centrifugal force. Then the condition of its steady revolution is $W : F :: z : y$; that is to say, $\frac{y}{z} = \frac{F}{W} = \frac{y\alpha^2}{g}$; consequently

$$z = \frac{g}{\alpha^2} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (69).$$

Or, if $n = \frac{\alpha}{2\pi} = \frac{\alpha}{6{\cdot}2832}$ be the number of turns or fractions of a turn in a second,

$$z = \frac{g}{4\pi^2 n^2} = \frac{0{\cdot}8165 \text{ foot}}{n^2} = \frac{9{\cdot}79771 \text{ inches}}{n^2} \quad . \quad . \quad (70);$$

$z$ is called the *altitude of the pendulum*.

If the rod of a revolving pendulum be jointed, as in fig. 33, not to a point in the vertical axis, but to the end of a projecting arm C, the position in which the bob will revolve will be the same as if the rod were jointed to the point O, where its prolongation cuts the vertical axis.

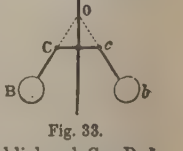

Fig. 33.

A revolving pendulum is an essential part of most of the contrivances called *governors*, for regulating the speed of prime movers.

The earlier kinds of governors act on the prime mover by the variations of their altitude. Thus in Watt's steam-engine governor the rods, through a combination of levers and linkwork C, *c*, D, *d* (fig. 32), act on a lever EF, which acts upon the throttle-valve for the admission of steam so as to enlarge or contract its opening when the speed becomes too small or too great.

In a more recent kind of governors invented by the Messrs Siemens, which may be called *differential governors*, the regulation of the prime mover is effected by means of the difference between the velocity of a wheel driven by it and that of a wheel regulated by a revolving pendulum. Fig. 34 illustrates this class of governors. A is a vertical dead-centre or fixed shaft, about which the after-mentioned pieces turn; C is a pulley driven by the prime mover, and fixed to a bevel-wheel, which is seen below it; E is a bevel-wheel similar to the first, and having the same apex. To this wheel are hung the bobs B, of which there are

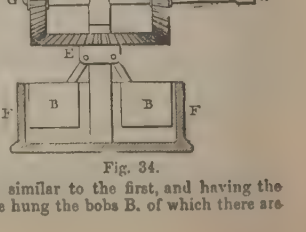

Fig. 34.

[1] This is a particular case of a more general principle, that *the motion of the centre of gravity of a body is not affected by the mutual actions of its parts*, for the proof of which see p. 718, § 179.

usually four, although two only are shown. Those bobs form sectors of a ring, and are surrounded by a cylindrical casing F. When the bobs revolve with their proper velocity, they are adjusted so as nearly to touch this casing; should they exceed that velocity, they fly outwards and touch the casing, and are retarded by the friction. For practical purposes their velocity of rotation about the vertical axis may be considered constant. G, G are horizontal arms projecting from a socket which is capable of rotation about A, and carrying vertical bevel wheels which rest on E and support C, and transmit motion from C to E. There are usually four of the arms G, G with their wheels, though two only are shown. H is one of those arms which projects, and has a rod attached to its extremity to act on the throttle-valve of a steam-engine, the sluice of a water-wheel, or the regulator of the prime mover, of whatever sort it may be.

When C rotates with an angular velocity equal and contrary to that of E with its revolving pendulums, the arms G, G remain at rest; but should C deviate from that velocity, those arms rotate in one direction or the other, as the case may be, with an angular velocity equal to one half of the difference between the angular velocity of C and that of E, and continue in motion until the regulator is adjusted so that the prime mover shall impart to C an angular velocity exactly equal to that of the revolving pendulums.

There are various modifications of the differential governor, but they all act on the same principle.

*Division* 3. *Working of Machines of Varying Velocity.*

124. *General Principles.*—In order that the velocity of every piece of a machine may be uniform, it is necessary that the forces acting on each piece should be always exactly balanced. Also, in order that the forces acting on each piece of a machine may be always exactly balanced, it is necessary that the velocity of that piece should be uniform.

An excess of the effort exerted on any piece, above that which is necessary to balance the resistance, is accompanied with acceleration; a deficiency of the effort, with retardation.

When a machine is being started from a state of rest, and brought by degrees up to its proper speed, the effort must be in excess; when it is being retarded for the purpose of stopping it, the resistance must be in excess.

An excess of effort above resistance involves an excess of energy exerted above work performed; that excess of energy is employed in producing acceleration.

An excess of resistance above effort involves an excess of work performed above energy expended; that excess of work is performed by means of the retardation of the machinery.

When a machine undergoes alternate acceleration and retardation, so that at certain instants of time, occurring at the end of intervals called *periods* or *cycles*, it returns to its original speed, then in each of those periods or cycles the alternate excesses of energy and of work neutralize each other; and at the end of each cycle the principle of the equality of energy and work stated in sect. 96, with all its consequences, is verified exactly as in the case of machines of uniform speed.

At intermediate instants, however, other principles have also to be taken into account, which are deduced from the second law of motion, sect. 89, as applied by the aid of the principles of sect. 90, to *direct deviation*, or acceleration and retardation.

125. *Energy of Acceleration and Work of Retardation for a Shifting Body.*—Let $w$ be the weight of a body which has a motion of translation in any path, and in the course of the interval of time $\Delta t$ let its velocity be increased at a uniform rate of acceleration from $v_1$ to $v_2$. The rate of acceleration will be

$$\frac{dv}{dt} = \text{constant} = \frac{v_2 - v_1}{\Delta t};$$

and (p. 698, § 104) to produce this acceleration a uniform effort will be required, expressed by

$$P = \frac{w \cdot (v_2 - v_1)}{g \Delta t} \quad . \quad . \quad . \quad . \quad . \quad . \quad (71).$$

(The product $\frac{wv}{g}$ of the mass of a body by its velocity is called its *momentum*; so that the effort required is found by dividing the increase of momentum by the time in which it is produced.)

To find the *energy* which has to be exerted to produce the acceleration from $v_1$ to $v_2$, it is to be observed that the *distance* through which the effort P acts during the acceleration is

$$\Delta s = \frac{v_2 + v_1}{2} \Delta t;$$

consequently, the *energy of acceleration* is

$$P \Delta s = \frac{w(v_2 - v_1)(v_2 + v_1)}{2g} = \frac{w(v_2^2 - v_1^2)}{2g} \quad . \quad . \quad . \quad (72),$$

being proportional to the increase in the square of the velocity, and *independent of the time.*

In order to produce a *retardation* from the greater velocity $v_2$ to the less velocity $v_1$, it is necessary to apply to the body a *resistance*, connected with the retardation and the time by an equation identical in every respect with equation 71, except by the substitution of a resistance for an effort; and in overcoming that resistance the body *performs work* to an amount determined by equation 72, putting $Rds$ for $Pds$.

126. *Energy Stored and Restored by Deviations of Velocity.*—Thus a body alternately accelerated and retarded, so as to be brought back to its original speed, performs work during its retardation exactly equal in amount to the energy exerted upon it during its acceleration; so that that energy may be considered as *stored* during the acceleration, and *restored* during the retardation, in a manner analogous to the operation of a reciprocating force (sect. 117).

Let there be given the mean velocity $V = \frac{1}{2}(v_2 + v_1)$ of a body whose weight is $w$, and let it be required to determine the fluctuation of velocity $v_2 - v_1$, and the extreme velocities $v_1$, $v_2$, which that body must have, in order alternately to store and restore an amount of energy E. By equation 72 we have

$$E = \frac{w(v_2^2 - v_1^2)}{2g}$$

which, being divided by $V = \frac{1}{2}(v_2 + v_1)$, gives

$$\frac{E}{V} = \frac{w(v_2 - v_1)}{g};$$

and consequently

$$v_2 - v_1 = \frac{gE}{Vw} \quad . \quad . \quad . \quad . \quad . \quad . \quad (73).$$

The ratio of this fluctuation to the mean velocity, sometimes called the *unsteadiness* of the motion of the body, is

$$\frac{v_2 - v_1}{V} = \frac{gE}{V^2 w} \quad . \quad . \quad . \quad . \quad . \quad . \quad (74).$$

127. *Actual Energy of a Shifting Body.*—The energy which must be exerted on a body of the weight $w$, to accelerate it from a state of rest up to a given velocity of translation $v$, and the equal amount of work which that body is capable of performing by overcoming resistance while being retarded from the same velocity of translation $v$ to a state of rest, is

$$\frac{wv^2}{2g} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (75).$$

This is called the *actual energy* of the motion of the body, and is half the quantity which in some treatises is called *vis viva*.

The energy stored or restored, as the case may be, by the deviations of velocity of a body or a system of bodies, is the amount by which the actual energy is increased or diminished.

128. *Principle of the Conservation of Energy in Machines.*—The following principle, expressing the general law of the action of machines with a velocity uniform or varying, includes the law of the equality of energy and work stated in sect. 99 for machines of uniform speed.

*In any given interval during the working of a machine, the energy exerted added to the energy restored is equal to the energy stored added to the work performed.*

129. *Actual Energy of Circular Translation—Moment of Inertia.*—Let a body of the weight $w$ undergo translation in a circular path of the radius $\rho$, with the angular velocity of deflexion $\alpha$, so that the common linear velocity of all its particles is $v = \alpha\rho$. Then the actual energy of that body is

$$\frac{wv^2}{2g} = \frac{w\alpha^2\rho^2}{2g} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (76).$$

By comparing this with the expression for the centrifugal force ($w\alpha^2/g$), it appears that the actual energy of a revolving body is equal to the potential energy $F\rho/2$ due to the action of the deflecting force along one-half of the radius of curvature of the path of the body.

The product $w\rho^2/g$, by which the half-square of the angular velocity is multiplied, is called the *moment of inertia* of the revolving body.

130. *Actual Energy and Moment of Inertia of Rotation—Radius of Gyration.*—See p. 732, §§ 234–237.

131. *Examples of Radii of Gyration.*—See p. 733, § 238.

132. *Fly-wheels.*—A fly-wheel is a rotating piece in a machine, generally shaped like a wheel (that is to say, consisting of a rim with spokes), and suited to store and restore energy by the periodical variations in its angular velocity.

The principles according to which variations of angular velocity store and restore energy are the same with those of sect. 126, only substituting *moment of inertia* for *mass*, and *angular* for *linear* velocity.

Let W be the weight of a fly-wheel, R its radius of gyration, $\alpha_2$ its maximum, $\alpha_1$ its minimum, and $A = \frac{1}{2}(\alpha_2 + \alpha_1)$ its mean angular velocity. Let

$$\frac{1}{S} \quad \frac{\alpha_2 - \alpha_1}{A}$$

denote the *unsteadiness* of the motion of the fly-wheel; the denominator S of this fraction is called the *steadiness*. Let $e$ denote the quantity by which the energy exerted in each cycle of the working of the machine alternately exceeds and falls short of the work performed, and which has consequently to be alternately stored by acceleration and restored by retardation of the fly-wheel. The value of this *periodical excess* is—

$$e = \frac{R^2 W(\alpha_2^2 - \alpha_1^2)}{2g} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (77),$$

from which, dividing both sides by $A^2$, we obtain the following equations:—

$$\left.\begin{aligned} \frac{e}{A^2} &= \frac{R^2 W}{gS} \\ \frac{R^2 W A^2}{2g} &= \frac{Se}{2} \end{aligned}\right\} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (78).$$

The latter of these equations may be thus expressed in words:—*The actual energy due to the rotation of the fly, with its mean angular velocity, is equal to one-half of the periodical excess of energy multiplied by the steadiness.*

In ordinary machinery S = about 32; in machinery for fine purposes S = from 50 to 60.

The periodical excess $e$ may arise either from variations in the effort exerted by the prime mover, or from variations in the resistance of the work, or from both these causes combined. When but one fly-wheel is used, it should be placed in as direct connexion as possible with that part of the mechanism where the greatest amount of the periodical excess originates; but when it originates at two or more points, it is best to have a fly-wheel in connexion with each of those points. For example, in a machine-work, the steam-engine, which is the prime mover of the various tools, has a fly-wheel on the crank-shaft to store and restore the periodical excess of energy arising from the variations in the effort exerted by the connecting-rod upon the crank; and each of the slotting machines, punching machines, rivetting machines, and other tools has a fly-wheel of its own to store and restore energy, so as to enable the very different resistances opposed to those tools at different times to be overcome without too great unsteadiness of motion.

According to the computation of General Morin, the periodical excess $e$ in steam-engines with single cranks is from $\frac{1}{10}$th to nearly $\frac{1}{4}$th of the energy exerted during one revolution of the crank. For a pair of steam-engines driving one shaft, with a pair of cranks at right angles to each other, the value of $e$ is one-fourth of its value for a single cranked engine of the same kind, and of the same power with the two combined.

The ordinary radius of gyration of a steam-engine fly-wheel is from three to five times the length of the crank-arm. (For further particulars on this subject, see STEAM-ENGINE.)

For tools performing useful work at intervals, and having only their own friction to overcome during the intermediate intervals, $e$ should be assumed equal to the whole work performed at each separate operation.

133. *Brakes.*—A brake is an apparatus for stopping and diminishing the velocity of a machine by friction, such as the friction-strap already referred to in sect. 112. To find the distance $s$ through which a brake, exerting the friction F, must rub in order to stop a machine having the total actual energy E at the moment when the brake begins to act, reduce, by the principles of sect. 105, the various efforts and other resistances of the machine which act at the same time with the friction of the brake to the rubbing surface of the brake, and let R be their resultant,—*positive* if resistance, *negative* if effort preponderates. Then

$$s = \frac{E}{F + R} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (79).$$

134. *Energy distributed between two Bodies—Projection and Propulsion.*—Hitherto the effort by which a machine is moved has been treated as a force exerted between a movable body and a fixed body, so that the whole energy exerted by it is employed upon the movable body, and none upon the fixed body. This conception is sensibly realized in practice when one of the two bodies between which the effort acts is either so heavy as compared with the other, or has so great a resistance opposed to its motion, that it may, without sensible error, be treated as fixed. But there are cases in which the motions of both bodies are appreciable, and must be taken into account,—such as the projection of projectiles, where the velocity of the *recoil* or backward motion of the gun bears an appreciable proportion to the forward motion of the projectile; and such as the propulsion of vessels, where the velocity of the water thrown backward by the paddle, screw, or other propeller bears a very considerable proportion to the velocity of the water moved forwards and sideways by the ship. In cases of this kind the energy exerted by the effort is *distributed* between the two bodies between which the effort is exerted in shares proportional to the velocities of the two bodies during the action of the effort; and those velocities are to each other directly as the portions of the effort unbalanced by resistance on the respective bodies, and inversely as the weights of the bodies.

To express this symbolically, let $W_1$, $W_2$ be the weights of the bodies; P the effort exerted between them; S the distance through which it acts; $R_1$, $R_2$ the resistances opposed to the effort overcome by $W_1$, $W_2$ respectively; $E_1$, $E_2$ the shares of the whole energy E exerted upon $W_1$, $W_2$ respectively. Then

$$\left.\begin{aligned} E &: E_1 : E_2 \\ :: \frac{W_2(P - R_1) + W_1(P - R_2)}{W_1 W_2} &: \frac{P - R_1}{W_1} : \frac{P - R_2}{W_2} \end{aligned}\right\} \quad . \quad . \quad (80).$$

If $R_1 = R_2$, which is the case when the resistance, as well as the effort, arises from the mutual actions of the two bodies, the above becomes,

$$\left.\begin{aligned} E &: E_1 : E_2 \\ :: W_1 + W_2 &: W_2 : W_1 \end{aligned}\right\} \quad . \quad . \quad . \quad . \quad . \quad (81);$$

that is to say, the energy is exerted on the bodies in shares inversely proportional to their weights; and they receive accelerations inversely proportional to their weights, according to the principle of dynamics, already quoted in a note to sect. 121, that the mutual actions of a system of bodies do not affect the motion of their common centre of gravity.

For example, if the weight of a gun be 160 times that of its ball, $\frac{159}{160}$ of the energy exerted by the powder in exploding will be employed in propelling the ball, and $\frac{1}{160}$ in producing the recoil of the gun, provided the gun up to the instant of the ball's quitting the muzzle meets with no resistance to its recoil except the friction of the ball.

135. *Centre of Percussion.*—It is obviously desirable that the deviations or changes of motion of oscillating pieces in machinery should, as far as possible, be effected by forces applied at their centres of percussion.

If the deviation be a *translation*,—that is, an equal change of motion of all the particles of the body,—the centre of percussion is obviously the centre of gravity itself; and, according to the second law of motion, if $dv$ be the deviation of velocity to be produced in the interval $dt$, and W the weight of the body, then

$$P = \frac{W}{g} \cdot \frac{dv}{dt} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (82)$$

is the unbalanced effort required.

If the deviation be a rotation about an axis traversing the centre of gravity, there is no centre of percussion; for such a deviation can only be produced by a *couple* of forces, and not by any single force. Let $d\alpha$ be the deviation of angular velocity to be produced in the interval $dt$, and I the moment of the inertia of the body; then $\frac{1}{2} I d(\alpha^2) = I \alpha d\alpha$ is the variation of the body's actual energy. Let M be the moment of the unbalanced couple required to produce the deviation; then, by equation 57, sect. 104, the energy exerted by this couple in the interval $dt$ is $M \alpha dt$, which, being equated to the variation of energy, gives

$$M = I \frac{d\alpha}{dt} = \frac{R^2 W}{g} \cdot \frac{d\alpha}{dt} \quad . \quad . \quad . \quad . \quad . \quad (83).$$

Now (fig. 35), let the required deviation be a rotation of the body BB about an axis O, not traversing the centre of gravity G, $d\alpha$ being, as before, the deviation of angular velocity to be produced in the interval $dt$. A rotation with the angular velocity $\alpha$ about an axis O may be considered as compounded of a rotation with the same angular velocity about an axis drawn through G parallel to O and a translation with the velocity $\alpha$. OG, OG being the perpendicular distance between the two axes. Hence the required deviation may be regarded as compounded of a deviation of translation $dv = OG \cdot d\alpha$, to produce which there would be required, according to equation 82, a force applied at G perpendicular to the plane OG—

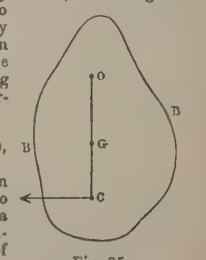

Fig. 35.

$$P = \frac{W}{g} \cdot OG \cdot \frac{d\alpha}{dt} \quad . \quad . \quad . \quad . \quad . \quad . \quad (84),$$

and a deviation $d\alpha$ of rotation about an axis drawn through G parallel to O, to produce which there would be required a couple of the moment M given by equation 83. According to the principles of statics, the resultant of the force P, applied at G perpendicular to the plane OG, and the couple M is a force equal and parallel to P, but applied at a distance GC from G, in the prolongation of the perpendicular OG, whose value is

$$GC = \frac{M}{P} = \frac{R^2}{OG} \quad . \quad . \quad . \quad . \quad . \quad . \quad (85).$$

Thus is determined the position of the centre of percussion C, corresponding to the axis of rotation O. It is obvious from this equation that, for an axis of rotation parallel to O traversing C, the

centre of percussion is at the point where the perpendicular OG meets O.

136. *Impact.*—Impact or collision is a pressure of short duration exerted between two bodies. For the detailed investigation of its laws the reader is referred to MECHANICS, p. 719, § 180 *sq.*

The effects of impact are sometimes an alteration of the distribution of actual energy between the two bodies, and always a loss of a portion of that energy, depending on the imperfection of the elasticity of the bodies, in permanently altering their figures, and producing heat. The determination of the distribution of the actual energy after collision and of the loss of energy is effected by means of the following principles :—

I. The motion of the common centre of gravity of the two bodies is unchanged by the collision.

II. The loss of energy consists of a certain proportion of that part of the actual energy of the bodies which is due to their motion relatively to their common centre of gravity.

Unless there is some special reason for using impact in machines, it ought to be avoided, on account not only of the waste of energy which it causes, but from the damage which it occasions to the frame and mechanism.

## CHAPTER III. PURPOSES AND EFFECTS OF MACHINES.

137. *Observing Machines and Working Machines.*—The present chapter must necessarily be limited to some very general observations on the principal classes into which machines may be divided, with reference to their purposes and effects, leaving details of particular examples for treatment under the respective special headings.

Machines may be divided, in the first instance, into two great divisions, viz. :—

I. *Observing Machines*, in which either the modification of motion alone, or the balancing of forces alone, is the object in view,—the performance of work being either null or incidental, and being limited to that which arises from the resistance of the machine.

II. *Working machines*, in which the performance of work is the main object.

138. *Classification of Observing Machines.*—Observing machines might very properly have been classed as *instruments*, being designed to aid the human senses and memory in obtaining and recording information. They may be divided, in the first instance, into four classes, according as the subject of observation by their aid is number, measure, or weight, into—

A. Counting machines.
B. Measuring machines.
C. Copying and drawing machines.
D. Weighing machines.

And to these may be added a fifth class, in which the functions of the first four are more or less combined, viz. :—

E. Recording machines.

139. (A.) *Counting Machines.*—The most important as well as the most common of counting machines are *time-keepers*, which count and indicate the numbers of oscillations of bodies which oscillate isochronously (viz., pendulums for clocks, balance-wheels for watches and marine chronometers) so as to measure time. In constructing such machines, the objects to be aimed at are the exact isochronism of the pendulum or balance, and the equable action of the motive power, so that it shall overcome the friction of the mechanism without affecting the rate.

Other counting machines count the oscillations of the beam of a steam-engine, or the revolutions of the cylinder of a gas-meter or of the wheel of a water-meter.

Others perform additions, subtractions, and multiplications, and of these the most elaborate kind (as, *e.g.*, that of Babbage) compute tables of functions by the addition of differences.

140. (B.) *Measuring Machines.*—Measuring machines are pieces of mechanism, by means of which the motion of some body of the nature of an index through some geometrical magnitude, such as a distance or an angle, is connected with some other motion, either equal or greater or smaller in some given ratio, and capable of being more readily compared with some standard of measure.

To this class belong all those astronomical and surveying instruments in which the motion of a line of sight (generally the line of collimation of a telescope) through a given angle is connected with the motion of an index or vernier round a corresponding arc of a graduated circle ; also those micrometers in which the advance of the end of a screw of fine pitch is measured by observing the simultaneous arc of rotation of a graduated circle attached to it.

Such micrometers have attained increased importance by the discovery of Whitworth,—that the mechanical magnifying of small distances by a train of screws affords a more accurate means of measurement than optical magnifying by the microscope,—and by the perfection to which that engineer has brought that art of accurate workmanship which is necessary in order to render mechanical magnifying possible.

Amongst measuring machines are included the *platometers* or *planimeters* of Sang, Morin, and Clerk Maxwell, which measure areas by means of mechanism. The amount of resistance in a measuring machine should be perfectly uniform, and sufficiently great to prevent accidental forces from disturbing the machine, without being so great as to render it inconveniently stiff. To combine these objects requires great accuracy of workmanship, together with strength and rigidity in the structure of the frame and mechanism.

141. (C.) *Copying and Drawing Machines.*—In copying machines for enlarging or reducing drawings there is usually a combination of levers and linkwork connecting a tracing-point, which is moved over the lines of the original figure, with a drawing-point, which draws the copy in such a manner that the velocity ratio of their motions is a given constant quantity, and that the directions of their motions make a constant angle.

Mechanism depending for its principle on the theory of the composition of rotations is used to draw ellipses, epicycloids, epitrochoids, and other curves.

142. (D.) *Weighing Machines.*—In weighing machines the motion of the mechanism is used only for the purpose that its cessation, or its becoming an oscillation about a certain position, may indicate the equilibrium of the forces applied to the machine. Those forces may either be weights, which are to be compared with each other, or forces of other kinds, to be compared directly or indirectly with weights.

The machine for comparing weights which is capable of the most minute accuracy is also the simplest, being the *balance*, in which the equality of two weights is ascertained by their balancing each other at the ends of a lever of equal arms. In the *steelyard*, consisting either of one lever or of a train of levers, the unknown weight has an unchangeable point of application, and is compared with a known weight by shifting the latter along the lever to which it is applied until the machine is balanced ; the ratio of the weights is then the reciprocal of the velocity ratio of their points of application. The steelyard is more convenient for weighing very heavy loads than the balance, but is not capable of such minute accuracy.

It is essential to accuracy in balances and steelyards that the friction should be less than the smallest admissible amount of error. To diminish the friction as much as possible, the axes of motion are all *knife-edges*, as they are termed, of steel or hardened iron, resting on hard surfaces of hardened iron or steel for ordinary purposes, and of some hard mineral, such as agate, for scientific purposes.

The weight of a column of fluid is determined by balancing it against a column of fluid whose weight is known, as in the barometer, where the weight of a column of the atmosphere is balanced against that of a column of mercury.

Weights are compared with each other indirectly, and other forces compared with weights, by means of their effects in bending a spring,—a convenient method, but not susceptible of minute accuracy.

The elastic pressure exerted by a fluid may be compared with weight, either by balancing the pressure against the weight of a column of a liquid, or by maintaining a piston in equilibrium against that pressure, by means of a weight pressing it directly, or of a weight acting through a steelyard, or of the elasticity of a spring which has been compared with weights.

143. (E.) *Recording Machines.*—Recording machines may be divided into two classes :—*self-registering instruments*, which, by the aid of clockwork, record measurements either of space or of force, together with the instants of time at which these measurements were made ; and *dynamometers*, already mentioned in Chap. II. of this article, which register measurements of force, together with the space through which it has acted, thus recording energy or work.

144. *Working Machines Classed.*—The object or purpose of working machines is to perform useful work ; and their classification relatively to their objects and purposes is founded on the kind of useful work which they perform. In this point of view they may be classed as follows :—

A. Machines for lifting or lowering solid weights.
B. Machines for the horizontal transport of weights, either combined or not with lifting or lowering.
C. Machines for projecting solids.
D. Machines for lifting fluids.
E. Machines for propelling or projecting fluids.
F. Machines for dividing bodies.
G. Machines for shaping bodies by removing portions of them.
H. Machines for shaping bodies by pressure.
I. Machines for uniting bodies into fabrics.
J. Machines for printing.
K. Machines for producing sound.
L. Miscellaneous machines.

It is not pretended that the above classification (taken to a considerable extent from the writings of Young and of Babbage) exhausts all kinds of machines ; it is brought forward merely as an attempt to introduce method to a certain extent into a subject which would otherwise be exceedingly confused.

145. (A.) *Machines for Lifting and Lowering Solids.*—The most common machines of this class are *capstans*, *cranes*, and *windlasses*.

They are usually worked by manual labour, but sometimes by hydraulic engines, or by steam-engines. The useful resistance, when a load is lifted, being the weight of that load, is in general greater than the effort exerted by the prime mover, so that the mechanism has to be adapted to giving the working-piece a less velocity than the piece to which the effort is applied. In lowering solid loads the weight of the load acts as the effort, and the energy exerted by it is expended in overcoming the friction of a brake in order that the speed of descent may not be excessive.

146. (B.) *Transporting Machines.*—The mechanism of transporting machines consists of two parts:—that by which the resistance is diminished, as the wheels and axles of vehicles; and that by which the resistance is overcome and the load propelled, comprising all kinds of locomotive and propelling machinery. In the present work transporting machines are treated of in the articles relating specially to the lines of conveyance to which they are applied.

147. (C.) *Machines for Projecting Solids.*—This class comprehends all kinds of artillery.

148. (D.) *Machines for Lifting Fluids.*—See HYDROMECHANICS.

149. (E.) *Machines for Propelling or Projecting Fluids.*—See the same article.

150. (F.) *Machines for Dividing Bodies.*—This class comprehends all machines for separating solid masses into parts, whether by digging, cutting, sawing, grinding, tearing, crushing, pounding, pressing out fluids, or otherwise; and whether applied to earth, stones, metals, timber, fruit, grain, fibres, or other materials.

151. (G.) *Machines for Shaping Bodies by Removing Portions of them.*—This class of machines to a certain extent resembles the preceding. It includes machines for cutting, grinding, and polishing blocks of stone into required figures, and for shaping pieces of wood, metal, or other material, whether by *turning*, to produce spherical, cylindrical, and other curved surfaces,—by *boring*, *punching*, *slotting*, or *gouging*, to produce cylindrical, rectangular, or other orifices and grooves,—by *screw-cutting*, by *planing*, by *grinding* and *polishing*, to produce curved or plane surfaces. The most difficult and important of all these operations is to produce a surface truly plane; and the perfecting of this operation by Whitworth is the most important step recently made in *Constructive Mechanics*, or the art of making machines and instruments. Next in point of difficulty may be placed the art of forming the concave reflecting surfaces of great specula for telescopes, such as those of the Herschels, of Lassell, and of Lord Rosse.

152. (H.) *Machines for Shaping Bodies by Pressure* comprehend, amongst others, *rolling-mills* for iron, *steam-hammers*, *wire-drawing* machines, *pinmaking* and *nailmaking* machines, *coining* and other *stamping* machinery, *brickmaking* machines, *presses* for packing and compressing, &c.

153. (I.) *Machines for Uniting Bodies into Fabrics* comprise *spinning* machinery, whether applied to ropes, yarn, or thread, *weaving* machinery of all kinds, *papermaking* machinery, *felting* machinery, and *sewing* machinery.

154. (J.) *Machines for Printing* are used to apply either colouring matters or matters for discharging colour to paper, cloth, and other materials.

155. (K.) *Machines for producing Sound.*—See ACOUSTICS and MUSIC.

156. (L.) *Miscellaneous Machines.*—There are numerous machines which perform processes, especially in the preparation of textile fabrics for the market, which it would be almost impossible to class. Examples of such machines will be found by referring to the articles relating to the various branches of manufacture.

## CHAPTER IV. APPLIED ENERGETICS, OR THEORY OF PRIME MOVERS.

157. *Prime Movers in general—Their Efficiency.*—Prime movers, or receivers of power, are those pieces or combinations of pieces of mechanism which receive motion and force directly from some natural source of energy. The point where the mechanism belonging to the prime mover ends and that belonging to the train for modifying the force and motion begins is somewhat arbitrary; in general, however, the mechanism belonging to the prime mover may be held to include all pieces which regulate or assist in regulating the transmission of energy from the source of energy. Thus, in the ordinary rotative steam-engine, the crank-shaft belongs to the prime mover, because it carries the eccentric which moves the valves and the fly-wheel which stores and restores the periodical excess of energy of the engine, and drives the governor (when there is one) which regulates the admission of steam.

The *useful work* of the prime mover is the energy exerted by it upon that piece which it directly drives; and the ratio which this bears to the energy exerted by the source of energy is the *efficiency* of the prime mover.

It is often convenient to divide the prime mover into sections, and resolve its efficiency into factors, each factor being the efficiency of one of those sections. Thus the efficiency of a steam-engine may be resolved into the following factors:—

*Efficiency of the furnace and boiler,*—being the proportion of the total heat of combustion of the fuel which takes effect in heating and evaporating the water.

*Efficiency of the steam in driving the piston,*—being the proportion of the energy exerted by the steam on the piston (called the *indicated* energy or power, as being measured by an indicator) to the mechanical equivalent of the heat received by the water.

*Efficiency of the mechanism from the piston to the crank-shaft inclusive,*—being the proportion of the effective energy transmitted by the crank-shaft to the indicated energy.

The product of those three factors is the efficiency of the engine as a whole.

In all prime movers the loss of energy may be distinguished into two parts,—one being the unavoidable effect of the circumstances under which the machine necessarily works in the case under consideration; the other the effect of causes which are, or may be, capable of indefinite diminution by practical improvements. Those two parts may be distinguished as *necessary loss* and *waste*.

The efficiency which a prime mover would have under given circumstances if the *waste* of energy were altogether prevented, and the loss reduced to necessary loss alone, is called the *maximum* or the *theoretical* efficiency under the given circumstances.

For some prime movers there is a combination of circumstances which makes the theoretical efficiency greater than any other combination does. The theoretical efficiency under those circumstances the *absolute maximum efficiency*.

The *duty* of a prime mover is its useful work in some given unit of time, as a second, a minute, an hour, a day. In some cases, such as that of the work of animals, the duty can be ascertained, while the efficiency can only be inferred indirectly or conjecturally from the want of precise data as to the whole energy expended.

58. *Sources of Energy Classed.*—The sources of energy used in practice may be classed as follows:—

A. Strength of men and animals.
B. Weight of liquids.
C. Motion of fluids.
D. Heat.
E. Electricity and magnetism.

159. (A.) *Strength of Men and Animals.*—The *mechanical daily duty* of a man or of a beast is the product of three quantities—the effort, the velocity, and the number of units of time per day during which work is continued. It is well known that for each individual man or animal there is a certain set of values of those three quantities which make their product, the daily duty, a maximum, and that any departure from those values diminishes the daily duty. Attempts have been made to represent by a formula the law of this diminution; but they have met with imperfect success. That which agrees on the whole best with the facts is the formula of Maschek, which is as follows:—let $P_1$ be the effort, $V_1$ the velocity, and $T_1$ the time of working per day, which give the maximum daily duty, and let P, V, T, be any other set of values of those quantities; then

$$\frac{P}{P_1}+\frac{V}{V_1}+\frac{T}{T_1}=3 \quad \ldots\ldots\ldots \quad (86).$$

One consequence of this formula is, that the best time of working per day for men, and for all animals, is *one-third part of a day*, or eight hours,—a conclusion in accordance with experience.

The best effort $P_1$, and the best velocity $V_1$, are much less certain,—the difficulty of determining their true mean values for particular species being rendered very great by the differences, not only between individuals, but between races or varieties of the same species. The following table of values is proposed by Maschek as approximately true:—

| Animals. | Weighing. | $P_1$. | $V_1$. | $\frac{T_1}{1600}$. | $P_1V_1$. | $P_1V_1T_1$. |
|---|---|---|---|---|---|---|
| | | lb. | Feet per second. | Hours per day. | Foot-lb per sec. | Foot-lb. |
| Man | 150 lb | 30 | 2·5 | 8 | 75 | 2,160,000 |
| Horse (draught) | 600 lb | 120 | 4·0 | 8 | 480 | 13,824,000 |
| Ox | 600 lb | 120 | 2·5 | 8 | 300 | 8,640,000 |
| Ass | 360 lb | 72? | 2·5 | 8 | 180 | 5,184,000? |
| Mule | 500 lb | 100? | 3·5 | 8 | 350 | 10,080,000? |

Of the numbers in this table those for the draught horse are probably the most accurate. For the thoroughbred horse it is certain that the value of $V_1$ is much greater, and that of $P_1$ much less, than for the draught horse,—the effect being probably that the *maximum* daily duty $P_1V_1T_1$ is nearly the same; but experimental data are wanting to determine these quantities with precision.

The following table, chiefly extracted from the works of Poncelet and Morin, with the addition of some results of experiments by Lieutenant David Rankine and by the author of this article, shows the daily duty of men and horses under certain specified circumstances:—

| | P. | V. | $\frac{T}{3600}$. | PV. | PVT. |
|---|---|---|---|---|---|
| | lb. | Feet p. sec. | Hours p. day. | Foot-lb per sec. | Foot-lb per day. |
| MAN— | | | | | |
| 1. Raising his own weight up stair or ladder..... | 143 | 0·5 | 8 | 72·5 | 2,088,000 |
| 2. Do. do. do..... | ... | ... | 10 | ... | 2,616,000 |
| 3. (Tread-wheel—see I)..... | | | | | |
| 4. Hauling up weight with rope | 40 | 0·75 | 6 | 30 | 648,000 |
| 5. Lifting weights by hand .... | 44 | 0·53 | 6 | 24·2 | 522,720 |
| 6. Carrying weights up stairs. | 143 | 0·13 | 6 | 18·5 | 399,600 |
| 7. Shovelling up earth to a height of 5 ft. 3 in. ..... | 6 | 1·3 | 10 | 7·8 | 280,800 |
| 8. Wheeling earth in barrow up slope of 1 in 12; horiz. veloc. 0·9 ft. per sec. (returning empty).. | 132 | 0·075 | 10 | 9·9 | 356,400 |
| 9. Pushing or pulling horizontally (capstan or oar) | 20·5 | 2·0 | 8 | 53 | 1,526,400 |
| 10. Turning a crank or winch | 12·5<br>18·0<br>20·0 | 5·0<br>2·5<br>14·4 | ?<br>8<br>2 min. | 62·5<br>45<br>288 | 1,296,000 |
| 11. Working pump..... | 19·2 | 2·5 | 10 | 33 | 1,188,000 |
| 12. Hammering..... | 15 | ? | ? | ? | 480,000 |
| HORSE— | | | | | |
| 13. (Thoroughbred) cantering and trotting, drawing a light railway carriage... | min. 22 5<br>max. 50 | 14·6 | 4 | 447·5 | 6,444,000 |
| 14. Horse (draught) drawing cart or boat, walking.... | 120 | 3·6 | 8 | 432 | 12,441,000 |

160. *Horizontal Transport.*—When men and animals carry burdens, or draw or propel loads in certain vehicles, it is difficult, and sometimes impossible, to determine the duty performed in foot-pounds of work, because of the uncertainty of the amount in pounds of the resistance overcome. In this case, for the purpose of comparing performances of the same kind with each other, a unit is employed called a *foot-pound of horizontal transport*, meaning the conveying of a load of 1 pound 1 foot horizontally. The following table, compiled from the sources referred to in sect. 159, gives some examples of the daily duty of men and horses in units of horizontal transport, L denoting the load in lb, V the velocity in feet per second, and T the number of seconds per day of working:—

| | L. | V. | $\frac{T}{3600}$. | LV. | LVT. |
|---|---|---|---|---|---|
| | lb. | Feet per second. | Hours per day. | lb conveyed 1 foot. | lb conveyed 1 foot. |
| MAN— | | | | | |
| 15. Walking unloaded, transport of own weight..... | 140 | 5 | 10 | 700 | 25,200,000 |
| Do. do..... | 140 | 6 | 10 | 840 | 30,240,000 |
| 16. Wheeling load L in two-wheeled barrow, returning empty; V=¼ velocity | 224 | 1·6 | 10 | 373 | 13,428,000 |
| 17. Do. one-wheeled barrow, do. | 135 | 1·6 | 10 | 225 | 8,100,000 |
| 18. Travelling with burden..... | 90 | 2·5 | 7 | 225 | 5,670,000 |
| 19. Conveying burden, returning unloaded..... | 140 | 1·6 | 6 | 233 | 5,032,800 |
| 20. Carrying burden for 30 seconds only..... | 252<br>126<br>0 | ...<br>11·7<br>23·1 | ...<br>...<br>... | ...<br>1474·2<br>0 | ...<br>...<br>... |
| HORSE— | | | | | |
| 21. Walking with cart always loaded..... | 1500 | 3·6 | 10 | 5400 | 194,400,000 |
| 22. Trotting do. do..... | 750 | 7·2 | 4½ | 5400 | 87,480,000 |
| 23. Walking with cart, going loaded, returning empty; V=½ mean velocity ..... | 1500 | 2 0 | 10 | 3000<br>972 | 108,000,000 |
| 24. Carrying burden, walking... | 270 | 3·6 | 10 | | 34,992,000 |
| 25. Do. trotting... | 180 | 7·2 | 7 | 1296 | 32,659,200 |

161. (B.) *Weight of Liquids.*—(C.) *Motion of Fluids.*—In water-wheels and other hydraulic engines the weight and motion of a liquid usually act together as sources of energy.

To determine the necessary loss of energy and the theoretical efficiency, we have the following formulæ:—

The *power* or *energy* exerted per second is

$$Q\left(H+\frac{V_1^2}{2g}\right);$$

the *necessary loss*—

$$Q\cdot\frac{V_2^2}{2g};$$

the *theoretical effect* or *useful work* per second—

$$Q\left(H+\frac{V_1^2-V_2^2}{2g}\right); \quad \ldots\ldots (87);$$

the *theoretical efficiency*—

$$\left(H+\frac{V_1^2-V_2^2}{2g}\right)\div\left(H+\frac{V_1^2}{2g}\right)$$

where Q denotes the weight of liquid which acts on the wheel or other engine per second; H the vertical fall from the point where the liquid first begins to act directly or indirectly on the wheel or other engine to the point where it ceases to act; $V_1$ the velocity of the liquid when it begins to act; and $V_2$ the least velocity, when it ceases to act, which will properly discharge the liquid, and prevent its accumulating so as to impede the wheel or engine.

(For details as to the actual efficiency and duty and the construction of hydraulic engines, see HYDROMECHANICS.)

In *windmills*, the air, being in motion, presses against and moves four or five radiating vanes or *sails*, whose surfaces are approximately helical, their axis of rotation being parallel, or slightly inclined in a vertical plane, to the direction of the wind. The best form and proportions for windmill sails, as determined experimentally by Smeaton, are as follows (see fig. 36):—

Angle of each sail with the plane of rotation—at DE = 18°;
Do. do. do. at BC = 7°;
OD = ⅓ of *whip* OA; bar DE = ⅓OA; bar BC = ⅓OA; AC = DE.

162. (D.) *Heat.*—In sect. 157 the three factors into which the efficiency of an engine moved by heat can be resolved have already been stated. The efficiency of the furnace and boiler in steam-engines varies from 0·4 to 0·85. It may be considered that the loss of heat to the extent of 0·15 by the chimney is necessary in order to produce a sufficient draught; any loss beyond this is *waste*. The theoretical efficiency of the *steam*, or *other elastic fluid*, which serves as the mechanism for converting heat into mechanical energy, is regulated by a law which will now be explained.

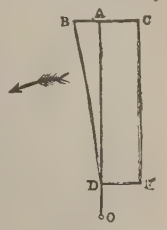

Fig. 36.

Heat acts on bodies in two ways—to elevate temperature and make the bodies hotter, and to produce mechanical changes. Heat employed in producing mechanical changes disappears or becomes *latent*, as it is termed, and can be reproduced by reversing those mechanical changes. When a cycle of mechanical changes, ending by the restoration of the body to its original condition, produces mechanical energy, heat disappears to an amount equal to that which would be generated by employing the mechanical energy in overcoming friction,—that is to say, a British unit of heat (or one degree Fahr. in one lb of liquid water) for every 772 foot-pounds of energy (being the constant already mentioned in sect. 115 as *Joule's equivalent*). This is called the *conversion of heat into mechanical energy*.

The *efficiency of the fluid* in a heat-engine is the proportion which the heat converted into mechanical energy bears to the whole heat received by the water or other fluid; and the *theoretical* or *maximum* value of that efficiency depends solely upon the respective temperatures at which the fluid receives heat and rejects the unconverted heat, according to the following law:—let $t_1$ represent the temperature at which the fluid receives heat, and $t_2$ the temperature at which it rejects the unconverted heat, as measured from the *absolute zero*,—that is, from a point 493°·2 Fahr. or 274° C. below the temperature of melting ice (temperatures so measured are called *absolute temperatures*); then the *maximum theoretical efficiency of the water or other fluid in a steam-engine or other heat-engine is*

$$\frac{t_1-t_2}{t_1}. \quad \ldots\ldots\ldots (88).$$

The necessary loss of heat by the fluid is $t_2/t_1$ of the whole heat received by it; and any loss beyond this is *waste*.

The theoretical efficiency of the steam in ordinary steam-engines seldom exceeds ¼th; the greatest actual efficiency is about ⅛th; the efficiency in good ordinary engines is about 0·1 or 0·08, and in bad and wasteful engines 0·04, or even less. (For details see STEAM-ENGINE.)

163. (E.) *Electricity and Magnetism.*—Electricity developed by chemical action in a galvanic battery has been to a small extent used to produce mechanical energy by alternately magnetizing and unmagnetizing soft-iron bars.

The data for determining the actual efficiency of such engines are deficient. Their theoretical efficiency depends on the following law demonstrated by Joule:—

Let $\gamma_1$ denote the strength of the electric current which would be developed in the conducting wire of the battery if there were no iron bar to be magnetized; $\gamma_2$ the strength to which the current is reduced by the reaction of the iron bar, tending to induce a contrary current. Then the theoretical efficiency of the engine is

$$\frac{\gamma_1-\gamma_2}{\gamma_1}. \quad \ldots\ldots\ldots (89).$$

The proportion of the energy expended which is *necessarily lost* is $\gamma_2/\gamma_1$, and is employed in producing heat in the conducting circuit.

This law is exactly analogous to that of the theoretical efficiency of heat-engines given in equation 88.

There is reason to believe that electromagnetic engines are capable of a higher efficiency than heat-engines; but the greater cost of the materials consumed renders them much less economical commercially. (W. J. M. R.)

MECHITHARISTS, a congregation of Armenian monks, in communion with the church of Rome, which has enjoyed papal recognition since 1712. Its founder Mechithar, or Mechitar da Pietro, a native of Sebaste (Sivas) in Armenia, was born on February 7, 1676; his original name was Manuk, which he exchanged for that by which he was subsequently known ("Comforter") when he entered the cloister of the Holy Cross in his native town. In the pursuit of knowledge he visited various seats of learning in Armenia, and in the years 1691, 1696, and 1699 respectively he attained the office of deacon, priest, and vartabed or doctor in theology. Having removed to Constantinople, he founded there in 1701 a religious institute for the intellectual, moral, and spiritual elevation of his countrymen, and for the cultivation of their language and literature. In 1703 sectarian jealousy obliged him to retire to the Morea, where he ultimately found a settlement at Modon, and built a cloister and church (1706–8). The outbreak of hostilities between the Turks and Venetians in 1715 compelled him to take refuge in Venice, where in 1717 he received from the senate the island of San Lazzaro, which ever since has been the home of his order. Mechithar, who died on April 27, 1749, was the author of a *Grammatica Armena*, printed in 1770, of an Armenian *Lexicon*, printed in 1744, of an Armenian translation of the Bible, printed in 1734, and of several commentaries on Biblical books. The order of Mechitharists, which, as already mentioned, received formal recognition (from Clement XI.) in 1712, uses the Armenian language and the Syrian rite; its rule resembles the Benedictine, prominent among the duties of its members being the proclamation of the gospel and the diffusion of good literature. They have accumulated at San Lazzaro a large library, specially rich in Armenian MSS.; and their linguistic attainments are considerable. Among their services to the cause of learning may be mentioned, in addition to the preparation of critical texts of the Armenian classics and of the Armenian version of the Bible, the publication in old translations of various works of Ephraem Syrus, Philo, and Eusebius, of which the originals have been lost. There are establishments belonging to the order elsewhere in Italy (Padua), as well as in Russia and Turkey, in Paris, in Austria-Hungary, and in Germany. Of these the most important is that of Vienna, which has existed since 1810, and has become a sort of learned "academy," receiving honorary members even from beyond the pale of the Roman Catholic Church.

MECHLIN, or MALINES, a city of Belgium, in the province of Antwerp, on the river Dyle, about 14 miles north of Brussels. The general aspect of the town, belted by a fine avenue of trees, with well-built houses, extensive gardens, and broad airy streets and squares of proverbial cleanliness, is pleasing to the eye; there is, however, a lack of life and motion, a repose bordering on stagnation; and the area occupied by the town is much too extensive for the population. Mechlin was for many centuries, and is to this day, the religious metropolis of Flanders, and its monuments and curiosities are in general of a sacred description. Among the most remarkable is the cathedral church of St Rombold or Rombaut, mainly built in the latter half of the 14th century; the square massive tower, rising 300 feet high and bearing four dials, each 48 feet in diameter, is visible from all the country round. The interior proportions of the edifice are grand, and it contains some fine works of art—statues of the apostles, standing against the pillars of the nave, Vandyck's picture of the Crucifixion, the Adoration of the Shepherds, by Erasmus Quellin, and others. The church of St John possesses a celebrated triptych of Rubens, and another by the same master is to be seen at Notre Dame. The "Halle" or market still retains some vestiges of the splendid palace raised on the site by Charles V. in 1530, and on the chief market-place is a monument erected to Margaret of Austria, daughter of the emperor Maximilian. Mechlin is an archiepiscopal see, occupied by a cardinal, primate of Belgium, deriving his spiritual power from Rome, and quite independent of (at times even openly opposed to) the civil Government. His palace is the headquarters of the Catholic party, and the seat of considerable moral and political influence extending over every parish in the land; the university of Louvain, the Catholic schools, more than four thousand in number, and the great seminary of Mechlin, the nursery of the Belgian priesthood, are entirely under the direction of the archbishop. The industrial activity of the town, formerly very great, has constantly decreased in the present century, and is now almost extinct. The important corporation of weavers was scattered by the political troubles of the 15th and 16th centuries; and the lace trade has gradually been transferred to Brussels and other towns. There still exist a few special manufactures, those of carved oak furniture, straw chairs, and wool and linen tissues being among the foremost; some tanyards and breweries are also to be found, and the means of communication furnished by the Dyle supply a tolerably brisk market in corn, oils, flax, hemp, and hops. As a railway station Mechlin possesses peculiar importance, being a junction of the chief Belgian Government lines and the great central workshop for constructing and repairing the rolling-stock. The population of Mechlin in 1880 was 42,381.

Mechlin appears to have been about the 8th century a mere group of cabins surrounding a noted monastery where St Rombaut, now the patron saint of the town, suffered martyrdom on the 24th of June 775. After having belonged to the first Frankish monarchs, it was given by Pippin the Little to his relative Adon, and passed, at the commencement of the 10th century, under the dominion of the bishops of Liége, in whose name it was governed by the powerful house of Berthold until the year 1333. When this family became extinct, Mechlin and the surrounding district were divided in two portions and sold by the bishops to the duke of Brabant and the count of Flanders, the former of whom, ten years later, once more united the whole territory under his own sway. By the marriage of Margaret of Brabant with Philip the Bold, Mechlin was brought under the sceptre of the house of Burgundy, whose fate it shared from that time. Stormed by the French in 1572, by the prince of Orange in 1578, by the English in 1580, the town suffered much during the wars of the 17th and 18th centuries. Napoleon I. had its fortifications razed in 1804, and made it the capital of the French "Département des deux Nèthes" until 1814, when it was comprised in the kingdom of the Netherlands, and it finally became part of Belgium in 1830.

MECKLENBURG, a territory in North Germany, on the Baltic Sea, extending from 53° 4′ to 54° 24′ N. lat., and from 10° 35′ to 13° 57′ E. long., corresponds with tolerable closeness to the old lower Saxon province of the same name, and is now unequally divided into the two grand-duchies of Mecklenburg-Schwerin and Mecklenburg-Strelitz. These are so closely related in history, political organization, natural features, and general development that it is convenient to treat them in a single article.

MECKLENBURG-SCHWERIN, the seventh state of the German empire in size and the eighth in population, is bounded on the N. by the Baltic Sea, on the W. by the principality of Ratzeburg and Lauenburg, on the S. by Brandenburg and Hanover, and on the E. by Pomerania and Mecklenburg-Strelitz. It embraces the duchies of Schwerin and Güstrow, the district of Rostock, the principality of Schwerin, and the barony of Wismar, besides several small "enclaves" in the adjacent territories. Its total area is about 5117 square miles.

MECKLENBURG-STRELITZ, the eleventh state of the German empire in area and the nineteenth in population, consists of two detached parts, the duchy of Strelitz on the east of Mecklenburg-Schwerin and the principality of

Ratzeburg on the west. The first of these is bounded by Mecklenburg-Schwerin, Pomerania, and Brandenburg, the second by Mecklenburg-Schwerin, Lauenburg, and the territory of the free town of Lübeck. Their joint area is 1126 square miles.

Mecklenburg lies wholly within the great North-European plain, and its flat surface is interrupted only by one range of low hills, intersecting the country from south-east to north-west, and forming the watershed between the Baltic Sea and the Elbe. Its highest point, the Helpter Berg, is 580 feet above the sea-level. The coast-line runs for 65 miles along the Baltic (without including indentations), for the most part in flat sandy stretches covered with dunes. The chief inlets are the bays of Wismar, Grosse Wiek, Salzhaff, and Kroy, and the roads of Warnemünde. The rivers are numerous though small; most of them are affluents of the Elbe, which itself traverses a small portion of Mecklenburg. Several of the streams are navigable, and the facilities for inland water traffic are increased by a tolerably extensive system of canals. Lakes are very numerous; about four hundred of fair size, covering an area of 500 square miles, are reckoned in the two duchies. The largest is Lake Müritz, 52 square miles in extent. The climate on the whole resembles that of Great Britain, but the winters are generally more severe; the mean annual temperature is 48° F., and the annual rainfall is about 28 inches. Although there are long stretches of marshy moorland along the coast, the soil is on the whole productive. According to the official returns of 1878, about 57 per cent. of the total area of Mecklenburg-Schwerin consisted of cultivated land, 17 per cent. of forest, and 13 per cent. of heath and pasture. In Mecklenburg-Strelitz the corresponding figures were 48, 20, and 9 per cent. Agriculture is by far the most important industry in both duchies. The following table shows the areas and products of the chief crops in 1880:—

| Crops. | Mecklenburg-Schwerin. | | Mecklenburg-Strelitz. | |
|---|---|---|---|---|
| | Acres. | Tons. | Acres. | Tons. |

Besides these, smaller areas are devoted to maize, buckwheat, pease, rape, hemp, flax, hops, and tobacco. The extensive pastures support large herds of sheep and cattle, including a noteworthy breed of merino sheep. The horses of Mecklenburg are of a fine sturdy quality, and are highly esteemed in Germany. In 1878 the two duchies contained 100,651 horses, 315,712 cattle, and 1,321,916 sheep. Red deer, wild swine, and various other kinds of game are found in the forests. The manufactures of Mecklenburg are of little importance. Its industrial establishments include a few iron foundries, wool-spinning mills, carriage and machine factories, dye-works, tanneries, brick-fields, soap-works, breweries, distilleries, numerous limekilns and tar-boiling works, tobacco and cigar factories, and about eight hundred mills of various kinds. Mining is also insignificant, though a fair variety of minerals is represented in the district. Amber is found on and near the Baltic coast. Trade, mainly confined to the larger duchy, is tolerably active. Rostock, Warnemünde, and Wismar are the principal commercial centres. The chief exports are grain and other agricultural produce, live stock, spirits, wood, and wool; the chief imports are colonial produce, iron, coal, salt, wine, beer, and tobacco. The horse and wool markets of Mecklenburg are largely attended by buyers from various parts of Germany. Fishing is carried on extensively in the numerous inland lakes. Within the last decade the mercantile fleet of Mecklenburg-Schwerin has doubled the number and quadrupled the tonnage of its ships, these consisting in 1881 of 370 sailing vessels and 11 steamers, with an aggregate burden of 112,388 tons. Mecklenburg-Strelitz has no seaboard.

Mecklenburg-Schwerin and Mecklenburg-Strelitz are both limited monarchies under grand-dukes, who are hereditary in the male line. The reigning families are closely related, and possess mutual rights of succession; should both families become extinct, their possessions pass to Prussia. The constitution, which is common to both the duchies, exhibits few traces of the liberal tendency of modern politics. The temporary modifications brought about by the agitation of 1848 were quickly rescinded, and matters returned to the old semi-feudal arrangements, which deprive the bulk of the people of all share in the government. The constitution as it now exists is based upon an agreement made between the duke of Mecklenburg-Schwerin and his estates in 1755, and adopted in the same year by Mecklenburg-Strelitz. The Landes-Union, or common assembly of the two duchies, consists of representatives of the Ritterschaft, or landed proprietors, and of the Landschaft, which embraces forty-seven towns. The peasantry is unrepresented, and the principality of Ratzeburg, in Mecklenburg-Strelitz, is governed directly by the grand-duke. The Landes-Union meets once annually, alternating between Sternberg and Malchin. When not sitting it is represented by a committee of nine members. Distinct from the Landes-Union are the convocation diet and the deputation diet, which are assemblies of the estates of one or other duchy for special business. In Mecklenburg-Schwerin the executive is placed in the hands of four ministers, holding the portfolios of foreign affairs, domestic affairs, finance, and justice (including education and religion). In Mecklenburg-Strelitz there is one minister, who is aided by a small council. In both duchies the military administration is in the hands of the crown. Mecklenburg-Schwerin has two votes in the federal council of the German empire, and sends six members to the imperial diet, while the smaller duchy has one representative in each assembly. As no official budget is published in either duchy, it is impossible to give accurate details of their financial position. In Mecklenburg-Schwerin it is usual to distinguish three branches of revenue, one under the control of the sovereign, one under the joint control of the sovereign and estates, and the third (of small amount) under the sole management of the estates. The income under the first heading is derived from the royal domains, the ordinary taxes, and special votes for special purposes, and amounts to about £600,000. With this sum are defrayed the ordinary expenses of government, including the annual contribution to the imperial treasury. The revenue under the second head is about £100,000. The public debt in 1880 amounted to £1,100,000. The revenues of Mecklenburg-Strelitz are unknown; its debt is estimated at about £300,000. The private income of the duke, derived from the royal domains, makes him one of the richest princes in Germany. The duchies of Mecklenburg contribute three regiments of infantry, a battalion of rifles, two regiments of dragoons, and four batteries of field artillery to the imperial army.

The educational institutions partake of the high character common to those of the German empire. The two duchies contain nine gymnasia, seven "Realschulen," three normal schools, and an adequate number of schools of a lower grade. There is a university at Rostock, which in 1882 had a teaching staff of 36 professors and an attend-

ance of about 250 students. In 1880–81 only 0·56 per cent. of the recruits in Mecklenburg-Schwerin were unable to read and write their names, while all the recruits in Mecklenburg-Strelitz were able to do both. The predominant confession in Mecklenburg is the Lutheran, which is professed by both the grand-dukes. The proportion of Roman Catholics, Jews, and members of the Reformed Church is insignificant. The ultimate spiritual authority is exercised by consistories at Schwerin and Strelitz. Mecklenburg also contains a fair share of learned societies and benevolent institutions. The supreme court of appeal for both duchies, in all criminal and civil cases, is at Rostock.

The population of Mecklenburg-Schwerin in 1861 was 548,449; in 1871, 557,707; in 1875, 553,785; and in 1880, 577,055. The capital is Schwerin (30,146 inhabitants), but the most important town is Rostock (36,967 inhabitants). The population of Mecklenburg-Strelitz in 1861 was 99,060; in 1871, 96,982; in 1875, 95,673; in 1880, 100,269. The chief town is Neu-Strelitz. About 71 per cent. of the inhabitants are engaged in agricultural pursuits. The proportion of the rural to the urban population is as 3 to 1, or exactly the reverse ratio to that in the neighbouring Prussia. The peasantry of Mecklenburg still retain numerous traces of their Slavonic origin, especially in their speech, but their peculiarities have been much modified by amalgamation with the German colonists who settled within this district at various times. The townspeople and nobility are almost wholly of Saxon strain. The slow rate of increase in the population of Mecklenburg is chiefly accounted for by the constant stream of emigration. Between 1870 and 1880 the two duchies contributed in the highest proportion to the emigration from Germany. Out of 595,151 German emigrants who sailed from Bremen, Hamburg, Stettin, and Antwerp within that period, 24,870 came from Mecklenburg-Schwerin and 2481 from Mecklenburg-Strelitz, representing respectively 4·38 and 2·52 per 1000 inhabitants as the yearly average. Probably another cause of the slow growth of population is to be sought for in the difficulties thrown in the way of the marriage of the peasants by the semi-feudal character of their tenure. It is a significant fact that in 1880 the proportion of illegitimate births in the two duchies amounted to 14 per cent. as compared with 9 per cent. in the entire German empire.

*History.*—The Vandals, who in the time of Tacitus occupied the region now known as Mecklenburg, were succeeded in the 6th century by a Slavonic race. Though partly conquered by Charlemagne in 789, this people soon regained their independence, and long offered a successful resistance to all attempts on the part of the German emperors to overcome and Christianize them. At last, in 1160, Duke Henry of Saxony made himself master of the country. The native prince was, however, permitted to retain his sovereignty, and has transmitted to his descendants and successors of the present day the distinction of being the only ruling princes of Slavonic origin in Germany. In 1160 he was raised by the emperor Frederick I. to the dignity of a prince of the empire. From 1202 till 1227 Mecklenburg was under Danish supremacy; and in 1229, two years after its restoration to Germany, there occurred the first of a long series of divisions of the territory, which, with subsequent reunions, constitute so much of its complicated history. In 1348 Charles IV. made Mecklenburg a duchy. In 1523 the trials and commotions springing from the rivalry and jealousy of two joint rulers incited the prelates, nobility, and burghers to form a union among themselves, the effects of which are visible to the present day,—most prominently in the existence of the common Landes-Union. The Reformation was welcomed by the inhabitants of Mecklenburg in 1524; and about 1555 nearly all the monasteries were suppressed. In 1621, when a new partition took place, the town of Rostock "with its university and high court" was declared to be held in common. The diet also retained its joint character, and henceforth alternated between Sternberg and Malchin.

In the Thirty Years' War both Mecklenburg-Schwerin and Mecklenburg-Güstrow—as the parts were then called—incurred the suspicion of the emperor, who secretly sold them to Wallenstein, and expelled the dukes in his behalf. They were reinstated, however, by Gustavus Adolphus, and at the peace of Prague in 1635 they both made their peace with the emperor. At the peace of Westphalia Rostock and some other parts of Mecklenburg territory were given in pledge to Sweden, and they were not redeemed till 1803. The sufferings of the Mecklenburg peasantry during the Thirty Years' War were exceeded in no other part of sorely-tried Germany. Most were reduced to serfdom through poverty; in some cases whole villages utterly vanished. In 1695 the Mecklenburg-Güstrow line became extinct; and, after some contention between the brother and the nephew of the last duke of Mecklenburg-Schwerin for the vacant succession, the "Hamburg Division" (March 8, 1701) apportioned to each shares that are represented by the present duchies. The affixes Schwerin and Strelitz are derived from the capital towns of the two dukes.

Mecklenburg-Schwerin began its new independent existence by a series of constitutional struggles between its nobility and its rulers. The heavy debt incurred by Charles Leopold, who had joined Russia in a war against Sweden, brought matters to such a pitch that in 1728 the emperor Charles VI. deposed the duke in favour of his brother Christian Louis. Under this prince, the "Rostock Contract," which is still the basis of the constitution, was framed in 1755. During the Seven Years' War Mecklenburg-Schwerin assumed a hostile attitude towards Frederick the Great, and was in consequence occupied by Prussian troops. In 1806 it was overrun by the French, and in 1808 it joined the confederation of the Rhine. The duke, however, though he assisted Napoleon in 1812, was the first member of the confederation to renounce it, and in the following year his troops fought against France and Denmark. On joining the Germanic confederation he assumed the title of grand-duke, with the style of royal highness. In and after 1848 the duchy witnessed a considerable agitation in favour of a new and more liberal constitution, but the subsequent reaction rescinded all the concessions that had been made, and reduced matters to their former feudal condition. In 1819 and 1820 serfdom and personal bondage were abolished, and various slight ameliorations of the state of the peasantry have since been introduced.

Mecklenburg-Strelitz adopted the constitution of the sister duchy by an "Agnitions-Act" in 1755. In 1806 it was spared the infliction of a French occupation through the interest of the king of Bavaria; but in 1813 it was mulcted in the sum of two million thalers for the French army. In 1808 it entered the Rhenish confederation, but repudiated it in 1813 and joined the alliance against Napoleon. In 1815 the duke assumed the title of grand-duke.

MEDALS. See NUMISMATICS.

MEDEA, the daughter of Æetes, king of the Colchians, who were believed to be of Egyptian descent (Herod., ii. 104), and are said to have found a settlement on the east of the Euxine and to the south of the Caucasus. Medea was one of the "wise women" (witches or sorceresses) of antiquity, and perhaps, like Helen, was a human embodiment of some goddess connected with Eastern element-worship, possibly with Hera. For the story of her love for Jason the Argonaut, and of the revenge she took for his desertion of her for another bride, a Corinthian princess, Glauce, daughter of Creon, see ARGONAUTS and JASON. A more interesting inquiry is the origin of the tale, and its connexion with solar myths.

The legend of the Argonautic expedition is a very ancient one. It is alluded to in the *Odyssey* (xii. 70), in more than one passage of Æschylus,[1] and is given at some length in the fourth Pythian ode of Pindar, the close agreement of which with the Alexandrine compilation by Apollonius Rhodius, entitled *Argonautica*, in four books, shows that, according to the general law of mythology, the main features of the legend differed but little. The original story, it is probable, was contained in a still older epic poem called ἡ Μινυὰς ποίησις, the authorship of which was ascribed to Prodicus of Phocæa.[2]

The "Golden Fleece," in quest of which the adventurers

[1] He alludes to Phineus and the *Lemnia facinora* (*Eum.* 50; *Cho.* 620), and there were plays composed by him on both these subjects.

[2] Pausan., iv. 33, 7. He quotes from it two hexameter verses in x. 28, 2.

made a voyage from the home of Jason, Iolchus in the Thessalian Magnesia, is virtually identical with the fiery robe which Medea prepared for her rival Glauce, the new bride, with the Homeric "ægis," and with the garment smeared with phosphorus which was sent by Deianira to Hercules, and burst into a flame when brought near to a sacrificial fire.[1] Jason, as the story went, was not allowed by the guardian of the fleece, King Æetes, to approach it till he had performed a certain task in putting to the yoke fire-breathing bulls, which he effected by the aid of Medea. The bull is a well-known symbol of the sun, and it occurs in the bull-slaying group representing the Persian sun-god Mithras. Again, the slaying of a father by a son (the old sun killed by the new one) is seen alike in Œdipus having caused the death of his father Laius, in Æson, the father of Jason, having been restored to life by the magic arts of Medea, and in Pelias having been killed and boiled in a caldron by his own daughters at the instigation of the sorceress. Lastly, the legend that Medea was herself the granddaughter of the Sun, and that she escaped in a car drawn by flying dragons, given to her for safety by her grandsire,[2] equally tends to prove that the whole story is of solar origin, and can be explained on that theory alone.

This, indeed, has been well stated by Sir G. W. Cox.[3] The "dragon chariot is simply the chariot of Indra, Helios, and Achilles; and it is drawn by dragons because the word denoted simply beings of keen sight, and was naturally applied to the creatures which may be supposed to bear the sun across the heaven."

In all these legends about the sun the performance of certain imposed "toils" or labours is included, the idea expressed being the hard necessity of the sun going his daily course in the appointed time in spite of thickening storm-clouds and opposing powers of darkness, through which he has to fight his way, both visibly above and invisibly underneath the earth. Thus Hercules has his twelve labours (the number corresponding to the lunar months), while Jason is not only required by his uncle King Pelias to bring the golden fleece, but is commanded by Æetes to tame the bulls as a condition of obtaining it. The name Μήδεια may possibly be referred to *μήδεσθαι*, "to care for," as Jason may contain the root *ἰᾶσθαι*, "to heal," which is the meaning that Pindar attaches to it,[4] or to *ἴον*, the violet-coloured dawn, as in Iocaste, Inmos, and Iolaus.[5] In his relation to the snake, which guarded the fleece, and to the dragons' teeth which he sowed on the ground ploughed by the fiery bulls, compared with the serpent entwining the staff of the healing god Asclepius, we see that almost invariable connexion that subsists between solar and phallic worship.[6] This view is confirmed by the "ship Argo," one of the many sexual symbols of cup-shaped and boat-like form.[7] It is the "ship" which was the Teutonic symbol of the goddess Isis.[8]

The existing literature on the love of Medea for Jason shows how popular was the story in antiquity for its pathos and its sentimentality. Thus the *Medea* of Euripides was rendered by Ennius; Neophron of Sicyon and Melanthius[9] wrote plays of the same name; we have the long and fine Pythian ode of Pindar, already referred to, the touching epistle "Medea Jasoni" in the *Heroides* of Ovid, and the interesting, beautiful, and too little read *Argonautica* of Apollonius.

Of course, the similarity of the names Μῆδοι and Μήδεια led to etymological speculations on the identity of the nomenclature, and one Medus, a son of Medea, was believed to have been an eponym hero.[10] The author of the compilation known as Hesiod's *Theogony* says that Medeus was a son of Medea by Jason,[11] and was brought up, as Jason himself had been, by Chiron in the mountains. Euripides assigns but two children to Medea and Jason,[12] and Apollodorus[13] gives their names as Mermerus and Pheres.

MEDELLIN, a town of Colombia, South America, capital of the state of Antioquia, is situated at a height of 4845 feet above the sea, in the valley of the Rio Porce, a right-hand tributary of the Rio Cauca, and, though 100 miles from the confluence, not more than 16 miles east from the valley of the larger stream. It is a clean and well-built place, but has no public buildings of note. Though the population is estimated at 14,000, there is no great activity except on the market days, twice a week, when the buyers and sellers flock in from the country. See Fr. von Schenck in *Petermann's Mittheil.*, 1880.

MEDFORD, a town of the United States, in Middlesex county, Massachusetts, at the head of navigation on Mystic river, and 5 miles north-west of Boston by a branch of the Boston and Maine Railroad. It is a busy place, with a considerable variety of manufactures—woollens, carpets, buttons, bricks, leather, &c. Tufts College, situated near the town on Walnut Hill, was founded by the Universalists in 1853, and named in honour of Charles Tufts, the donor of the 70 acres occupied by the building and its grounds. The endowment amounts to more than $1,000,000. The population of Medford was 5717 in 1870 and 7537 in 1880.

MEDHURST, Walter Henry (1796–1857), one of the most distinguished Protestant missionaries to the Chinese, was born in London in 1796. His education began at St Paul's Cathedral school. As he grew up, he learned the business of a printer; and, having become interested in missions to the heathen, he sailed in 1816 for the London Missionary Society's station at Malacca, which was likely to be a great printing-centre. His linguistic powers soon showed themselves. He became proficient in Malay, in a knowledge of the written characters of Chinese, and in the colloquial use of more than one of its dialects. He was ordained at Malacca in 1819, and was in all missionary labours "more abundant,"—first at Penang, then at Batavia, and finally at Shanghai. To give only the names of his various works, some in English, some in Chinese, would take a considerable space. A dictionary of one of the Fuh-Kien dialects is still valuable; and his Chinese-English and English-Chinese dictionaries (Batavia, 1842) are more complete and reliable than any earlier or later works of the same kind. After the conclusion of the first English war with China he removed to Shanghai in 1843, and there he continued till 1856, laying the foundations, broad and deep, of a successful mission. His principal labour for several years, as one of a committee of delegates of whom he was *facile princeps*, was in the revision of existing Chinese versions of the Sacred Scriptures. The result was what should be called a new version of the Bible, marvellously correct in idiom, and faithful to the meaning of the original. The university of New York conferred upon him in 1843 the degree of D.D. Medhurst left Shanghai in 1856, with several members of his family, to try the effect of a visit to England for his failing health. He died, however, two days after reaching London, on the 24th January next year. Strong, sprightly, versatile, and genial, he was a man of extraordinary gifts and generous soul. No efforts (and many were made) could draw him from his devotion to the work of missions.

MEDICAL JURISPRUDENCE, or, as it is now more usually termed, FORENSIC MEDICINE, is that branch of state medicine which treats of the application of medical knowledge to the purposes of the law. The term medical jurisprudence, though sanctioned by long usage, is not an appropriate one; since the subject is, strictly speaking, a branch of medicine rather than of jurisprudence; it does not properly include sanitation or HYGIENE (*q.v.*), both this and medical jurisprudence proper being distinct branches of state medicine. The connexion between medicine and the law was perceived long before medical jurisprudence was recognized, or had obtained a distinct appellation. It first took its rise in Germany, and subsequently, but more tardily, received recognition in Great Britain.

Forensic medicine, or medical jurisprudence proper as distinguished from hygiene, embraces all those questions which bring the medical man into contact with the law, and embraces (1) questions affecting the civil rights of individuals, and (2) injuries to the person.

### I. QUESTIONS AFFECTING THE CIVIL OR SOCIAL RIGHTS OF INDIVIDUALS.

1. *Development of the Human Frame.*—The development of the physical and mental powers of the human being is a matter of the highest importance, and is a factor of great consequence in determining criminal responsibility, civil responsibility, or the power of giving validity to civil contracts, and in determining the personal identity of a living person or of a corpse. Human life is usually divided into the five periods of *infancy*, *childhood*, *youth*, *manhood*, and *old age*. Some writers increase the number of these, unnecessarily, to seven periods, without any practical advantage.

*Infancy* is the period from birth till the first or milk set of teeth begin to be shed—usually about the seventh year. During this period the body increases in size and stature more, relatively, than at any other period of existence; and the mental faculties undergo great development. The milk teeth, twenty in number, are evolved in a definite order, beginning with the central incisors at about six months, and ending with the second molars about the termination of the second year. From the size and stature of the body, the development of the teeth, and the more or less advanced state of ossification or solidification of the bony skeleton, conclusions may be drawn as to the probable age of the infant.

*Childhood* extends from the commencement of the shedding of the milk teeth to the age of puberty—usually from the seventh to the fourteenth or fifteenth year. During this period the body expands, as well as the bony structures, without any clearly marked difference in structure being observable between the sexes except as regards the genitals, so that it is impossible to distinguish absolutely between the male and the female skeleton during this period. The milk-teeth are shed, and are replaced by the second or permanent set, thirty-two in number, though these do not usually all make their appearance during childhood. Marked differences between the proclivities of the sexes are noticeable even at an early period of childhood, and long before the characteristic functions begin to be developed.

*Youth* is marked at its commencement by the changes which occur at puberty—the development of the genitals in both sexes, the appearance of hair on the genitals, the appearance of a beard in the male, the development of the breasts in the female, the appearance of the monthly flow in the female, and the ability to secrete semen in the male. Marked mental changes now occur, and the generative functions are perfected. Youth terminates at the age of legal majority, twenty-one years; or perhaps the period ought to be extended to twenty-five years of age, as it is with some nations.

*Manhood* (or *Womanhood*) is the period of perfection of all the bodily and mental powers. It ceases in woman with the cessation of the monthly flow at about forty-five years of age; but in man it often extends to a much later period of life.

*Old Age* begins with the decay of the bodily and mental faculties, and is characterized by wrinkling of the skin, loss of the teeth, whitening of the hair, and feebleness of the limbs. In its later stages decay of the mental faculties, deafness, obscurity or loss of vision, and bowing of the spine are added.

2. *Duration of Human Life.*—The chances of human life form an important subject of inquiry, which has been elucidated by the labours of Price, Milne, Farr, and others; and on deductions from comparisons of birth and death rates is founded the system of annuities, insurance against loss in sickness, and the insurance of lives. Since the establishment of corapulsory registration of deaths, our knowledge of the ordinary and extraordinary chances of human life has been much extended, and surer data are now available for calculations of probabilities of life, of survivorships, and of the payments which ought to be made in benefit clubs. See INSURANCE and LONGEVITY.

3. *Personal Identity.*—It might be imagined that there is little danger, with the exercise of ordinary care, of mistaking one person for another; but the remarkable case of the Tichborne claimant, and some other less-known but perhaps equally singular instances, have demonstrated that mistakes as to the identity of individuals are easily made, and are more frequent than is commonly supposed. Where the identity has to be established or disproved after long absence, exposure to foreign climates and great hardships, wounds, &c., the problem is often one of extreme difficulty. The data for identifying a person are individual and family likeness, stature, the colour of the eyes, peculiarities of garb and manner, recollection of antecedent events, but more especially marks on the person either congenital or acquired. Such are *nævi* or mother's marks, scars, and disunited or badly united fractures, known to have existed upon the missing person. An accurate solution of the question is, nevertheless, often a matter of the greatest difficulty.

4. *Marriage.*—Under this head the medical jurist has to deal principally with the nubile age, viewed in the light of nature and according to legislative enactments, and with such physical circumstances as affect the legality of marriages, or justify divorce.

In Great Britain the age at which the sexes are first capable of propagating the species is later than in more southern climes. Ordinarily it does not occur before fifteen years of age for the male and fourteen for the female; exceptionally, however, it occurs at the ages of thirteen and of twelve (or even less) respectively in the male and female. By legislative enactment, nevertheless, parents and guardians may, in England at all events, forbid the marriage of young people till the age of legal majority. The only physical circumstances which in Great Britain form a bar to marriage are physical inability to consummate, and the insanity of one of the parties at the time of marriage. Both those circumstances have been pleaded and sustained in the law courts. In other countries minor physical circumstances, as disease, are held to invalidate marriage.

5. *Impotence and Sterility.*—These may arise from organic or from functional causes,—the former being alone irremediable, and as such taken cognizance of by the law courts. On this subject it is unnecessary to enlarge here

6. *Pregnancy.*—This subject presents one of the widest fields for medico-legal evidence. The limits of age between which it is possible, the limits of utero-gestation, and the signs of pregnancy may all in turn be the subjects of investigation.

The limits of age between which pregnancy is possible are usually fixed by the appearance and cessation of the monthly flow; and these ordinarily begin about fourteen and cease at forty-five years of age. Exceptionally they appear as early as the tenth year, and may not cease till the end of the fifth decade of life. Cases, however, have occurred where a woman has conceived before menstruating; and a few doubtful cases of conception are recorded in women upwards of fifty, or even sixty, years of age. The general fact of pregnancy being limited by the age of puberty on the one hand and the cessation of the monthly flow—or fifty years as the extreme limit of age—must be accepted as the safest guide in practice.

The limits of utero-gestation are not in England fixed by legislation. The French code fixes the extreme limit of three hundred days. The ordinary period is forty weeks and a half, or two hundred and eighty-three days from the cessation of the last monthly flux. The limit of three hundred days, as fixed by the French code, is perhaps never exceeded, if ever reached. The uncertainty of females in fixing the exact date of conception has given rise to the discrepant opinions of physiologists on the subject. It is well known, however, that among the higher animals the period is not a precise one; and impregnation and conception are doubtless not necessarily coincident.

The signs of pregnancy are of the utmost importance to the medical jurist. He may be called upon to pronounce upon the virtue of a female, to sustain or rebut a plea for divorce, to determine whether a capital sentence shall be carried out, or to determine whether it is probable that an heir will be born to an estate. Should he err in his judgment—and mistakes are very possible in the earlier months of utero-gestation—he may commit a grievous wrong. Medical jurists are in the habit of classifying the signs of pregnancy as uncertain or certain; it is the former which are most regarded by the public, but the latter are alone of probative value to the jurist. The usual and uncertain signs are the cessation of the monthly flow, nausea, sickness, a darkening of the areola and the formation of a secondary areola around the nipple, enlargement of the breasts, increased size of the abdomen, the formation of a tumour in the womb, quickening, and the motions of the fœtus. There are also other minor signs of less importance. The certain signs are the uterine souffle, which is a peculiar soft sound heard over the abdomen, and synchronous with the maternal pulse; ballottement, or the examination for a floating tumour in the abdomen between the fifth and eighth months of pregnancy; and the pulsations of the fœtal heart, heard by means of the stethoscope. These pulsations are much quicker than, and not synchronous with, the maternal pulse. This is the only indubitable sign of pregnancy. It is inapplicable before the fourth month of gestation.

7. *Parturition.*—The *imminence* of the process of parturition is of comparatively little interest to the medical jurist; but the *signs of recent delivery* are all-important. These signs are the bruised, swollen, and lacerated state of the external genitals, relaxation and dilatation of the vagina and womb, the existence of a peculiar vaginal discharge known as the lochia, a relaxed and fissured condition of the abdominal walls, a peculiar aspect of the countenance, and the distended state of the breasts due to the secretion of milk. The lochial discharge is the most characteristic sign. All the signs may disappear within ten days of delivery, though this is not usual.

Connected with parturition, the question of *viability* of the child is not unimportant. After the intra-uterine age of seven months is reached a child is certainly viable. The period at which the fœtus becomes viable cannot be stated with certainty; but five calendar months, or one hundred and fifty days, is perhaps the nearest approximation which can be made. The viability of a child is judged by its size and weight, its general state of development, the state of the skin, hair, and nails, its strength or feebleness, the ability to cry, and its power of taking maternal nourishment. The question of viability has important bearings upon the crime of infanticide, and the succession to property.

The subject of *superfœtation*, or the possibility of two conceptions having occurred resulting in the birth of twins with a considerable intervening interval, is a very obscure one, and has given rise to much controversy,—its existence being affirmed by some medical jurists, and denied by others. There is much, however (*e.g.*, the existence of a double or bifid womb), to countenance the view that a double conception is possible.

In the curious case of a man marrying a woman having possession of an estate of inheritance, and by her having issue born alive and capable of inheriting her estate, the man on the death of his wife holds her lands for life as a tenant by the "curtesy" of England. Here the meaning of "born alive" is different from the meaning of the same expression as used respecting infanticide. In questions of tenancy by the curtesy it has been decided that any kind of motion of the child, as a twitching and tremulous motion of the lips, is sufficient evidence of live-birth. As regards infanticide, proof of a conclusive separate existence of the child is demanded before live-birth is admitted.

8. *Monsters and Hermaphrodites.*—To destroy any living human birth, however unlike a human creature it may be, is to commit a crime. Blackstone states that a monster which hath not the shape of mankind hath no inheritable blood; but the law has not defined a monster, nor what constitutes a human form. The same author states that if, in spite of deformity, the product of birth has human shape, it may be an heir. Hermaphrodites are beings with malformations of the sexual organs, simulating a double sex. Physiologists do not admit, however, the existence of true hermaphrodites with double perfect organs, capable of performing the functions of both sexes.

9. *Paternity and Affiliation.*—These are often matters of great doubt. A considerable time may elapse between the absence or death of a father and the birth of his reputed child. As has already been said, three hundred days is the utmost limit to which physiologists would extend the period of utero-gestation. This subject involves questions respecting children born during a second marriage of the mother, posthumous children, bastardy, and alleged cases of posthumous children.

10. *Presumption of Survivorship.*—When two or more persons perish by a common accident, when a mother and her new-born child are found dead, and in a few analogous cases, important civil rights may depend upon the question which lived the longest; and great ingenuity has been displayed in elucidating the disputes which have arisen in the law courts in such cases.

11. *Maladies Exempting from Discharge of Public Duties* frequently demand the attention of the medical man. He may be called upon to decide whether a man is able to undertake military or naval service, to act as a juryman without serious risk to life or health, or to attend as a witness at a trial. An endeavour to give a fearless and honest certificate should animate the medical man in the discharge of this delicate duty.

12. *Feigned and Simulated Diseases* often require much

skill and acuteness in order to detect the imposture. Where there is reason to suppose that a disease is simulated, much caution as to procedure is also required.

13. *Insanity or Mental Alienation.*—This subject presents an enormous field to the medical jurist. A medical man may be required to give evidence in any of the law courts, civil, criminal, or ecclesiastical, before commissions *de lunatico inquirendo*, or before a magistrate, as to the sanity or insanity of an individual; and he may have to sign certificates of unsoundness of mind with the view of providing for the safe custody and proper treatment of a lunatic. Hence he must be familiar with the chief forms of insanity (see INSANITY), and be able to distinguish and treat each of these. He will also be required to detect feigned insanity, and to examine persons charged with crime with the view of preventing real lunatics from being treated as criminals.

The terms "unsoundness of mind," applied to the condition of the mind itself, and "*non compos mentis*" to the person whose mind is affected, are legal terms applied to insanity. Lawyers have disputed as to whether imbecility should or should not be included under the head of insanity; but medical men include under this category all disorders or defects of the mind which disqualify a person for managing his affairs, and entering into a binding contract, or which render the individual morally irresponsible for his or her otherwise criminal actions. There is good legal authority for recognizing four forms of unsoundness of mind—*idiocy, dementia, mania*, and *monomania*.

The chief questions respecting unsoundness of mind which present themselves to the medical jurist are—is the person of sound or unsound mind; if unsound, are there real lucid intervals; is he fit to manage his affairs, to contract a marriage, or to execute a will; is he dangerous to others?

As grounds for restraint, the law recognizes only these conditions—danger to himself, inability to manage his own affairs and property, and danger to the person of others. Before an individual can be placed under restraint in an asylum the certificates of two medical men must be obtained, and the formal order of a relation or friend. The certificates to be valid must be signed by legally qualified medical practitioners having no interest, direct or indirect, in the patient, or in the asylum to which he is to be sent. The medical examiners must pay separate visits, each medical man examining the patient separately. The certificates, which remain valid for seven days only, must bear the exact address of the lunatic, his occupation, and the date of the examination; they must also set forth distinctly the grounds of the opinion they express, under the separate heads of facts observed by the examiner, and facts (to be specified) communicated by others. In the case of pauper lunatics one medical certificate only is required, which is supplemented by an order from a justice of the peace. In urgent cases also one medical certificate suffices for incarceration in an asylum, provided that within three days of the patient's reception two other such certificates are signed by two other medical practitioners, not being connected with the asylum, upon a like examination. The superintendent or proprietor of the asylum must in all cases forward to the commissioners of lunacy a notice of admission within one clear day from the patient's admission. Any infringement of the statutory regulations subjects the person who commits it to a heavy penalty.

### II. INJURIES TO THE PERSON.

1. *Defloration.*—The signs of defloration are obscure and uncertain; and it is rather by the coexistence of several of the usual marks than the existence of any one sign, that any just conclusion can be arrived at.

2. *Rape.*—This crime consists in the carnal knowledge of a woman forcibly and against her will. The resistance must be to the utmost, else the crime of rape has not been committed in the legal sense of the word. The proofs of rape, accordingly, apart from the consistency of the woman's story, mainly depend on the presence of the signs of defloration, and on marks of injury on the man.

3. *Mutilation.*—This may consist in the cutting or maiming of any member; castration is the most important, and perhaps but rarely effected as a crime. Self-mutilation, giving rise to false accusations, is occasionally resorted to.

4. *Criminal Abortion.*—The crime of abortion consists in unlawfully administering to a woman, or causing to be taken by her (whether she be with child or not), with intent to procure her miscarriage, any poison or noxious thing, or using for the same purpose any instrument or other means whatsoever; also in the use of the same means, with the same intent, by any woman being with child.

5. *Homicide.*—The legal sense of the term homicide excludes such injuries as are the result of either accident or of suicide. It embraces murder or wilful homicide, manslaughter or culpable homicide, casual homicide, and justifiable homicide.

As a preliminary in all cases of homicide, it is the duty of the medical jurist in the first place to ascertain the fact of death, and to distinguish between real and apparent death; and then to determine, if possible, the period at which death took place.

*Infanticide* or child murder is by the British law treated with the same severity as the murder of an adult. Indeed infanticide as a crime distinct from murder has no legal recognition. Practically this severity defeats itself, and offences which are really cases of child murder are often treated simply as cases of concealment of birth. The iniquity of the old law which threw the onus of proof of still-birth on the mother now no longer exists, and the law demands strict proof of live-birth at the hands of the prosecution. Hence the subject involves very nice points of forensic medicine. The child must be proved to have arrived at the period when there was a probability of its living (proof of viability); and as the establishment of respiration is necessary to prove live-birth the evidences of this act must be carefully investigated. The size and position of the lungs, and the state of the vessels concerned in fœtal circulation, must be carefully noted. The fœtal lungs are dark, dense, and liver-like in appearance and consistence, and sink when immersed in water; whilst the fully respired lungs are rosy, marbled, and soft and crepitant when handled. Minor degrees of respiration are recognized by the appearance of little groups of dilated air-vesicles, and by the fact that, although the lungs as a whole may sink in water, certain portions of them, into which respired air has penetrated, float in water even after subjection to firm pressure in the hand. Care must be taken, nevertheless, to exclude buoyancy of the lung due to putrefaction; in this case the air may be expelled by gentle pressure, and the previously buoyant portion of lung now sinks in water. It is impossible, however, to distinguish certainly between a lung naturally inflated and one artificially insufflated.

It must be borne in mind that, although live-birth cannot be affirmed in the absence of signs of respiration, the presence of these signs is not proof of live-birth in the legal sense of the term. The law demands for live-birth a separate existence of the child after delivery; and breathing may take place whilst the child is still either wholly or partially within the maternal passages, and in some special cases whilst still within the womb itself.

When proofs of respiration—it may be to such an extent as to leave no doubt as to live-birth—have been found, the cause of death is then to be investigated. Wounds, and other forms of injury, must be sought for. There may be signs of strangulation, suffocation, puncture of the fontanelles, and consequent injury to the brain, the administration of a poison, or other means of procuring death. It must be borne in mind that some of these causes may be brought about by omission, or even by accident. Thus strangulation may arise from natural and unrelieved pressure of the navel string on the neck of the child; suffocation from immersion of the face of the child in the maternal discharges, or by pressure of clothes on the mouth. Death may result from hæmorrhage through neglect to tie the navel string, or the infant may perish from exposure to cold.

In the case of exposed infants it is very important to ascertain the real mother. As such exposure usually takes place soon after birth, comparison of the age of the infant with the signs of recent delivery in the suspected mother is the best method of proving the relation.

Ordinary *homicide* may be accomplished by several modes that may sometimes be ascertained by examination of the body. Of one of the most important of these consideration is deferred to the article POISONS.

Death by *asphyxia* is a common mode of accomplishing homicide, as by suffocation, drowning, hanging, strangulation, or by exposure to mephitic air. Suicide and accidental death from these causes are still more common. (1) *Drowning* is thought to produce death occasionally by the suddenness of the shock causing suspension of the functions of circulation and respiration—by shock without a struggle. The usual mode of death appears, however,

to be by the circulation of unoxygenated blood through the brain acting as a poison upon that organ; and this is attended with all the phenomena of asphyxia, as in suffocation. The phenomena attending asphyxia are as follows. As soon as the oxygen in the arterial blood, through exclusion of air, sinks below the normal, the respiratory movements grow deeper and at the same time more frequent; both the inspiratory and expiratory phases are exaggerated, the supplementary respiratory muscles are brought into play, and the breathing becomes hurried. As the blood becomes more and more venous, the respiratory movements continue to increase both in force and frequency. Very soon the expiratory movements become more marked than the inspiratory, and every muscle which can in any way assist in expiration is brought into play. The orderly expiratory movements culminate in expiratory convulsions; these violent efforts speedily exhaust the nervous system, and the convulsions suddenly cease and are followed by a period of calm. The calm is one of exhaustion; all expiratory active movements have ceased, and all the muscles of the body are flaccid and quiet. But at long intervals lengthened deep inspiratory movements take place; then these movements become less frequent; the rhythm becomes irregular, so that each breath becomes a more and more prolonged gasp, which becomes at last a convulsive stretching of the whole body; and with extended limbs and a straightened trunk, with the head thrown back, the mouth widely open, the face drawn, and the nostrils dilated, the last breath is taken. The above phenomena are not all observed except in cases of sudden and entire exclusion of air from the lungs. In slow asphyxia, where the supply of air is gradually diminished (*e.g.*, in drowning), the phenomena are fundamentally the same, but with minor differences. The appearances of the body after death from drowning are various. There may be pallor of the countenance, or this may be livid and swollen. The air passages are filled with frothy mucus, and there may be water in the stomach. The ends of the fingers are often excoriated from grasping at objects; and weeds, &c., are sometimes found grasped in the hands. The distinction between murder and suicide by drowning can rarely be made out by examination of the body alone, and is usually decided from collateral circumstances or marks of a struggle. Attention must also be paid to the existence of wounds on the body, marks of strangulation on the neck, and the like. (2) *Hanging* may result in death from asphyxia, or, as is more particularly the case in judicial hanging, some injury is inflicted on the upper portion of the spinal cord, resulting in instant death. The ordinary appearances of death from asphyxia may be found: dark fluid blood, congestion of the brain, intensely congested lungs, the right cavities of the heart full, and the left comparatively empty of blood, and general engorgement of the viscera. Ecchymosis may be found beneath the site of the cord, or a mere parchmenty appearance. There may even be no mark of the cord visible. The mark, when present, usually follows an oblique course, and is high up the neck. The fact that a body may be suspended after death, and that if this be done speedily whilst the body is still warm there may be a *post-mortem* mark undistinguishable from the mark observed in death from hanging, must not be forgotten. (3) *Suffocation* may occur from the impaction of any substance in the glottis, or by covering up the mouth and nose. It is frequently of accidental origin, as when substances become accidentally impacted in the throat, and when infants are overlaid. The phenomena are those of pure asphyxia, which have already been detailed. On *post-mortem* examination the surface of the lungs is found covered with minute extravasations of blood, known as punctated ecchymosis. (4) *Strangulation* may be accomplished by drawing a cord tightly round the neck, or by forcibly compressing the windpipe (throttling). Hence there may be either a circular mark round the neck, not so oblique as after hanging, or the marks of the fingers may be found about the region of the larynx. The cartilaginous structures of the larynx and windpipe may be broken. The mark of the ligature is often low down in the neck. The signs of asphyxia are present in a marked degree. (5) *Mephitism.*—Death from the inhalation of irrespirable gases is a mode of assassination seldom employed, but is frequently resorted to on the Continent by suicides, charcoal fumes being commonly used for the purpose (see POISONS).

6. *Death from Starvation.*—Cases occur in which it is important to distinguish this from other modes of death. In such cases the skin becomes harsh and dry, and may acquire a peculiar odour; the subcutaneous fat disappears; the gums shrink away from the teeth; the tongue and mouth become dark-coloured and dry; the eyes are bloodshot; the intestines become thin and their coats translucent; the gall-bladder is distended. The period of total abstinence from food required to kill an adult is unknown, and greatly depends upon whether there be access to liquid. In some cases persons have been able to subsist on little or no nourishment for long periods, the body being in a state of quasi-hibernation.

7. *Death from Extremes of Temperature.*—(1) Death from cold is not often observed in the British Isles. A portion only of the body, as the extremity of a limb, may perish from extreme cold. After the first sensation of tingling experienced on exposure to severe cold, loss of sensation supervenes, with languor and an irresistible propensity to sleep. The tendency to this forms an extreme danger in such cases. (2) Death from extreme heat usually occurs in the form of burning and scalding, attended with destruction of a large portion of the cutaneous structures. Here the cause of death is obvious. The human body is capable of exposure to very hot air—as is seen in Turkish baths—for a considerable period with impunity. Sun-stroke is a cerebral affection brought on by too great exposure to a hot atmosphere, especially whilst undergoing fatigue.

8. *Death by Lightning.*—Lightning or an artificial electric current may cause instant death. No visible marks of the effects of the electric current may be left, or the body may be singed or discoloured, or the skin may be perforated at one or two spots.

9. *Wounds.*—The examination of wounds, whether fatal or not, often becomes an important branch of forensic medicine. Wounds are usually divided into *contused*, *lacerated*, *incised*, *punctured*, and *gunshot* wounds. For poisoned wounds see POISONS. Each kind of wound requires to be minutely examined and described, as they are in approved works on surgery. The degree of danger from each should be familiar to the medical jurist; and he should recollect that there is no wound which may not become incidentally fatal from improper treatment, peculiarities of constitution, or accidental inoculation with septic material. Punctured wounds or stabs require minute attention; for there have been instances in which death has been produced by an instrument so small as a pin thrust into a vital part. *Wounds of the head* are always dangerous, especially if the blow has been severe. The person so wounded may die without division of the skin, or fracture of the bones, as happens in what is known as *concussion* of the brain. Contusions which do not divide the skin may fracture the skull; or the inner table of the skull may be fractured without the outer being broken or depressed. Even wounds of the scalp may prove fatal, from inflammation extending towards the brain. Punctured wounds of the head are more dangerous than cuts, as more likely to excite fatal inflammation. When the brain and its membranes are injured, all such wounds are generally fatal. Wounds of the face or organs of sense are often dangerous, always disfiguring, and productive of serious inconvenience. *Wounds of the neck* are always very serious wherever more than the skin is divided. The danger of opening large blood-vessels, or wounding important nerves, is imminent; even the division of a large vein in the neck has proved immediately fatal, from the entrance of air into the vessel, and its speedy conveyance to the heart. A blow on the neck has instantly proved fatal, from injury to an important nerve, generally the pneumogastric or the sympathetic. Dislocations and fractures of the bones of the neck prove instantly fatal. *Wounds of the chest* are always serious when the cavity is penetrated, though persons may recover from wounds of the lungs, and have even survived for some time considerable wounds of the heart. This last is an important fact; because we are not always to consider the spot where the body of a person killed by a wound of the heart, and apparently remaining where he fell, is found as that in which the fatal wound was inflicted. Instances have occurred of persons surviving severe wounds of the heart for several days. Broken ribs are never without danger; and the same may be said of severe contusions of the chest, from the chance of inflammation extending inwards. Wounds penetrating both sides of the chest are generally considered as fatal; but possibly there may be recovery from such. *Wounds of the abdomen*, when they do not completely penetrate, may be considered as simple wounds, unless when inflicted with great force, so as to bruise the contents of the abdominal cavity; in that case they may produce death without breach of surface, from rupture of some viscus, as sometimes happens from blows or kicks upon the belly. Wounds injuring the peritoneum are highly perilous, from the risk of severe inflammation. Wounds of the stomach or intestines, or of the gall-bladder, generally prove mortal, from the effusion of their contents into the peritoneal cavity producing fatal inflammation. Wounds of the liver, spleen, or kidneys are generally soon mortal, from the great vascularity of those organs. Wounds of the extremities, when fatal, may generally be considered so from excessive hæmorrhage, from the consequences of inflammation and gangrene, or from the shock to the system when large portions of the limb are forcibly removed, as in accidents from machinery, and in wounds from firearms.

10. *Poisonous Food.*—Under certain conditions, various articles of diet, especially butcher meat, eggs, milk, butter, cheese, and honey, may become possessed of poisonous properties, and this may arise from a variety of causes besides the introduction of known and specific poisons. Moreover, certain kinds of animal food—fish chiefly—may have definite toxic properties. Food may be more or less poisonous—(1) from unsoundness, either from putridity or decomposition or disease; (2) from the presence of parasites; (3) from mouldiness, or presence of deleterious microscopic fungi; and (4) where the flesh is that of animals which have fed on noxious plants,—and under this head may also be classed poisonous honey, which bees have gathered from poisonous plants. (5) It may be of the nature of poisonous fish, using the term fish in the popular sense. (6) Certain fungi or mushrooms are poisonous. Parasitic diseases would, strictly speaking, come under the first head; but the pre-

ventive measures to be adopted in the use of food infested with parasites will alone be treated of in this place.

(1) *Poisonous Vegetables.*—Unsound or even rotten vegetables and fruits may be consumed, and become fertile sources of varied forms of poisoning, especially in hot summers. The symptoms produced by the ingestion of large quantities of unsound fruit or vegetables are of a diarrhœal character, not often of an alarming severity, except in the cases of the young and feeble. They may, however, sometimes attain a fatal severity. The cause is usually obvious, and the treatment is simple; mild purgatives, as rhubarb or castor oil, with or followed by opiates, to remove peccant matters from the intestines; and stimulants, as ammonia or alcohol, if there be much collapse. Certain fungi or mushrooms are known to be specifically poisonous, such as the *Amanita muscaria*, or fly-fungus, and others. Certain kinds of mushrooms, usually innocuous, are occasionally poisonous or deleterious; and the cause of this is not always clear. Poisonous fungi produce narcotic and irritant symptoms.

(2) *Poisonous, Tainted, or Putrid Meat.*—The obvious characteristics of good sound flesh meat are that its colour is red—neither pale pink nor deep purple; that it is marbled in appearance; firm and elastic to the touch, scarcely moistening the fingers; having a slight and not unpleasant odour; and that when exposed to the air for a day or two it should neither become dry on the surface nor wet and sodden. Sound meat is acid to litmus paper; unsound meat may be neutral or alkaline. Meat may be tainted with physic administered to the animal. It is a common practice, when a fat and valuable animal is unwell, to physic it, and if its recovery be not speedy to slaughter it. The meat of such animals may often be met with in our markets, and may induce illness from the physic with which it is contaminated. The effects of simple putridity are most varied. It is well known that some nations habitually eat putrid meat, and even prefer it to fresh; and the development of rottenness in eggs for the epicure is an art in China. There is no doubt that habit has much to do with the tolerance by the stomach of putrid meat, whether cooked or uncooked. But tainted game, and indeed all kinds of meat in which putrefaction has commenced, may indubitably produce disease. This is chiefly of a diarrhœal character, preceded by rigors, and attended with collapse and, it may be, convulsions and other signs of a profound affection of the nervous system. The effects of such tainted meat are slight as compared with those which are produced by the sausage-poison, developed by a sort of modified putrefaction in certain German sausages. These sausages, when they become musty and soft in their interior, nauseous in odour and flavour, and strongly acid to test paper, acquire a highly poisonous character, and are frequently fatal in their effects. The symptoms produced by the use of poisonous flesh are gastric pain, vomiting, diarrhœa, depression, coldness of the limbs, and weak irregular action of the heart. Fatal cases end in convulsions and oppressed respiration, death ensuing from the third to the eighth day. The nature of the sausage-poison, which is probably akin to that of putrid and indeed all non-specifically tainted meats, has been a matter of considerable controversy. Some have held that the poisonous action is due to the development of rancid fatty acids; others believe that a so-called catalytic body is produced, capable of setting up by contact a similar catalytic action. Others have regarded the sausage-poison as due to the formation of pyrogeneous acids during the drying or smoking of the sausages. The recent discovery by Selmi of a class of poisonous alkaloids or amides, termed *ptomaines*, developed during putrefaction of animal matters, on the one hand, and the discovery by Ballard and Klein, still more recently, that the fatally poisonous properties of hams prepared according to the American method may be due to the presence of a parasitic bacillus, point to one or other of these two latter causes as that of the effects of sausage-poison. Others again have referred the effects to the presence of a microscopic fungus—*Sarcina botulina*.

The poisonous nature of the flesh of animals which have fed on certain plants—for example, hares which have fed on certain species of rhododendron, pheasants on the kalmia shrub, &c.—has been abundantly demonstrated, and need only be referred to here. The honey from bees which have garnered on poisonous plants, as the azalea, may likewise be deleterious; and the fact is of classic interest. The milk even of goats which have browsed on poisonous herbs has also proved poisonous.

(3) *Diseased Meat.*—The poisonous effects of meat affected with certain parasites—trichinæ, cysticerci, trematodes, &c., is an undoubted fact. Great quantities of meat pass through our markets which is undoubtedly the flesh of animals affected with disease, such as foot-and-mouth disease, pleuro-pneumonia, pig typhoid, the so-called scarlatina of swine, sheep-pox, &c.; and the question is quite undecided as to whether such flesh produces any injurious effects. To stop the sale of such meat would be to cut off large sources of our meat supplies. The evils attending the use of such diseased meat, when well cooked, have undoubtedly been exaggerated; but, on the other hand, there is enough evidence to show that the use of certain kinds of diseased meat may be followed by serious results. Thus it is generally admitted that the flesh of animals which have suffered from pleuro-pneumonia and murrain will give rise to boils and carbuncles. Braxy mutton may also produce disease when eaten. Trichinæ will produce trichinosis, flukes, the tape-worm, &c. Hams are occasionally fatally poisonous; and this has been traced to the presence of certain low organisms known as *bacilli*.

(4) *Poisonous Fish.*—Fish is sometimes a poisonous article of food. Cases of poisoning by the so-called shell-fish of the British islands are not unfrequently met with. Generally it is the eating of crabs, lobsters, and mussels which produces such results. These are usually of a distressing rather than of a serious character, nettle-rash being a common symptom. Occasionally, however, fatal results have ensued from the use of mussels. In tropical seas poisonous fish are more plentiful—the golden sardine, the bladder fish, the grey snapper, &c.; and, these being eaten by larger fish, as the barracuda, perch, globe-fish, conger eel, &c., the latter may in turn become poisonous.

Good cookery, that is, exposure to a sufficiently high temperature for a sufficiently lengthened time, is undoubtedly the best measure to adopt short of absolute destruction of unsound and diseased meat. So long as meat is high-priced, and the effects of diseased meat so little understood and so undefined, it will be impossible to induce medical officers of health and sanitary inspectors to seize all the diseased and unsound meat which is daily offered for sale. Notwithstanding all that has been said to the contrary, experienced observers are pretty well agreed that thorough exposure of the meat throughout to the temperature at which albumen is coagulated is destructive to the parasites of flesh. Smoking is less effective. Salting is more effective than smoking; but there is some evidence to show that salting may merely hold the life of organisms in suspense without entirely destroying their vitality; and thus in the conversion of salted pork into hams—a process of re-salting and subsequent drying—the specific germ (a bacillus) has been known to be again rendered harmful. It is not known whether efficient cooking entirely removes the deleterious effects of flesh affected with other than parasitic disease, as for example pleuro-pneumonia.

The curative measures for the results of eating poisonous food cannot be specifically described. They are those which must be arrived at on general principles. Symptoms are to be treated, and the powers of the patient sustained until the deleterious matter is removed by the ordinary channels, or the trichinæ have become encysted.

## History of Forensic Medicine.

The true origin of medical jurisprudence is of comparatively recent date, although traces of its principles may be perceived in remote times. Among the ancient Greeks the principles of medical science appear only to have been applied to legislation in certain questions relating to legitimacy. In the writings of Galen we find, however, remarks on the differences between the fœtal and the adult lungs; he also treats of the legitimacy of seven months' children, and discusses feigned diseases. Turning to Rome, we find that the laws of the Twelve Tables fix three hundred days as the extreme duration of utero-gestation. It is doubtful whether the Roman law authorized medical inspections of dead bodies. In the code of Justinian we find *De Statu Hominum*; *De Pœnis et Manumissis*; *De Sicariis*; *De Inspiciendo Ventre Custodiendoque Partu*; *De Muliere quæ peperit undecimo mense*; *De Impotentia*; *De Hermaphroditis*,—titles which show obvious traces of a recognized connexion between medicine and law. It was not, however, by the testimony of living medical witnesses that such questions were to be settled, but on the authority of Hippocrates.

Medical jurisprudence, as a science, dates only from the 16th century. In 1507 the bishop of Bamberg introduced a penal code in which the necessity of medical evidence in certain cases was recognized; and in 1532 the emperor Charles V. persuaded the diet of Ratisbon to adopt an uniform code of German penal jurisprudence, in which the civil magistrate was enjoined in all cases of doubt or difficulty to obtain the evidence of medical witnesses,—as in cases of personal injuries, infanticide, pretended pregnancy, simulated diseases, and poisoning. The true dawn of forensic medicine dates, however, from the publication in 1553 of the *Constitutio Criminalis Carolina* in Germany. A few years later Weiher, a physician, having undertaken to prove that witches and demoniacs are, in fact, persons subject to hypochondriasis and hysteria, and should not be punished, aroused popular indignation, and was with difficulty rescued from the flames by his patron, William duke of Cleves.

At the close of the 16th century Ambrose Paré wrote on monsters, on simulated diseases, and on the art of drawing up medico-legal reports; Pineau also published his treatise on virginity and defloration. About the same time as these stimuli to the study of forensic medicine were being made known in Paris, the first systematic treatise on the science appeared in Sicily in the form of a treatise *De Relationibus Medicorum* by Fidele. Paulo Zacchia, the illustrious Roman medical jurist, moreover, published from 1621

to 1635 a work entitled *Quæstiones Medico-Legales*, which marks a new era in the history of the science,—a work which displays an immense amount of learning and sagacity in an age when chemistry was in its infancy, and physiology very imperfectly understood. The discovery of the circulation of the blood by Harvey soon followed, and gave a new impetus to the study of those branches of forensic medicine having direct relations to physiology; and to Harvey we owe the idea how to apply Galen's observations on the differences between the fœtal and the adult lungs to the elucidation of cases of supposed infanticide. About this time, too, Sebiz published two treatises, on the signs of virginity and on the examination of wounds respectively. In the former he contended that the hymen was the real mark of virginity; but this was denied by Augenio and Gassendi. In 1663 Bartholin, a Danish physician, investigated the period of human uterine gestation, a subject which had engaged the attention of Aristotle. He also proposed the "hydrostatic test" for the determination of live-birth—a test still in use, and applied by observing whether the lungs of an infant float or sink in water. Swammerdam explained the rationale of the process in 1677; but it was not till 1682 that it was first practically applied by Jan Schreyer.

Germany, ever the leader in questions of forensic medicine, introduced the first public lectures on medical jurisprudence. Michaelis gave the first course about the middle of the 17th century in the university of Leipsic; and these were followed by the lectures of Bohn, who also published *De Renunciatione Vulnerum; cui accesserunt Dissertationes binæ de partu enecato, et an quis vivus mortuusve aquis submersus, strangulatus, aut vulneratus fuerit*, and *De Officiis Medici Duplicis, Clinici et Forensis*. Welsch and Amman wrote on the fatality of wounds, and Licetus on monsters.

From the time of Ambrose Paré the mode of conducting investigations in forensic medicine had attracted attention in France; and in 1603 Henry IV. authorized his physician to appoint persons skilled in medicine and surgery to make medico-legal inspections and reports in all cities and royal jurisdictions; in 1692, difficulties having arisen, Louis XIV. created hereditary royal physicians and surgeons for the performance of like duties. These, having become a corrupt and venal body, were suppressed in 1790. The only works on forensic medicine which appeared in France during the 17th century, however, were Gendry's *Sur les Moyens de bien rapporter à Justice*, and Blégny's *Doctrine des Rapports en Chirurgie*. At the beginning of the 18th century the latter was superseded as a text-book by Devaux's *L'art de faire des rapports en Chirurgie*. Valentini followed with two works, which were finally incorporated in his *Corpus Juris Medico-Legale* which appeared in 1722. This work is a vast storehouse of medico-legal information, and a summary of the knowledge of the time.

Professorships for teaching the subject were founded in the German universities early in the 18th century, and numerous treatises on forensic medicine were published. Teichmeyer's *Institutiones Medicinæ Legalis* long formed the text-book of the subject; and Alberti, professor of legal medicine at Halle, in his *Systema* gave to the world a most complete and laborious treatise on the science. His industrious collection of facts renders his works a precious mine of information. Indeed towards the close of last century the Germans were almost the only cultivators of legal medicine. But in France the celebrated case of Villeblanche attracted attention to the subject, and called forth Louis, who in a memoir on utero-gestation attacked with powerful arguments the pretended instances of protracted pregnancy, and paved the way for the adoption in the *Code Napoleon* of three hundred days as the limit of utero-gestation, a period in precise accordance with the ancient Roman law of the Twelve Tables. Louis also wrote on death from hanging, and pointed out the mode by which we may distinguish murder from suicide under such circumstances. It is he who is credited with having been the first in France to publicly teach the just application of medical knowledge to jurisprudence. Fodéré's celebrated *Traité de Médecine Légale* appeared in 1798, and marks a new era in the annals of legal medicine.

No British author wrote systematically on forensic medicine till 1788, when Dr Samuel Farr published a short treatise on the *Elements of Medical Jurisprudence*; but this was merely an abridgment of an earlier work of Fazelius. Previous writers, as Mead, Munro, Denman, Percival, and the two Hunters, had, however, dealt with fragments of the subject; nevertheless the science as a whole was little appreciated or recognized in this country during the last century.

In the present century France took the lead; and the institution of three professorships of forensic medicine at the end of the 18th century produced excellent fruits. In 1814 Orfila, a Spaniard by birth, but naturalized in France, published his *Toxicologie*, a work which revolutionized this branch of medical jurisprudence, and first placed the knowledge of poisons upon a scientific basis. Since the time of Orfila, France has never ceased to have one or more living medical jurists, among the most recent of whom we must enumerate Tardieu, whose treatises on abortion, on poisons, on wounds &c., are justly celebrated. Germany too has industriously pursued the subject, and Casper's great work on forensic medicine will ever remain a classic in the science. In Russia Dragendorff has greatly contributed to our knowledge of poisons.

Though forensic medicine may be said to have been entirely neglected in England till the beginning of the present century, its progress has since been by no means slow or unimportant; and the subject now forms a recognized and obligatory portion of medical study. The first lectures delivered in Great Britain were given in the university of Edinburgh in 1801 by the elder Dr Duncan; and the first professorship was held by his son in 1803. Dr Alfred Swaine Taylor gave the first course of lectures delivered in England, at Guy's Hospital in 1831; and in 1863 the university of London made forensic medicine a separate subject for examination and honours for medical graduates. In 1822 there was not in the English language any treatise of authority either on medical jurisprudence or on any important division of the subject; for it was not till the following year that the useful compendium of Paris and Fonblanque was published; and even half a century ago medical jurisprudence may be said to have been almost in its infancy as compared with what it is now. Since 1829 Great Britain has produced an abundant crop of literature on forensic medicine. Sir Robert Christison's admirable treatise on *Toxicology*, Dr A. S. Taylor's *Principles and Practice of Medical Jurisprudence*, the same author's *Elements of Medical Jurisprudence*, Dr Guy's *Forensic Medicine*, and Ogston's *Lectures on Medical Jurisprudence* are well-known and widely circulated works. The separate memoirs of Taylor, Christison, Guy, and others are also storehouses of facts and deductions in the science.

America, too, has not been behind hand in the race. Wharton and Stillé's *Manual* and Wormley's *Toxicology* are the best-known works of American authors. (T. S.*)

MEDICI. This family is renowned in Italian history for the extraordinary number of statesmen to whom it gave birth, and for its magnificent patronage of letters and art. It emerged from private life and rose to power by means of a very subtle policy that was persistently pursued from generation to generation. The origin of the family is buried in obscurity. Some court historians indeed declare it to have been founded by Perseus, and assert that Benvenuto Cellini's bronze Perseus holding on high the head of Medusa was executed and placed in the Loggia dei Lanzi to symbolize the victory of the Medici over the republic. But this only proves that the real origin of the family is unknown, and equally unknown is the precise signification of the Medicean arms—six red balls on a field of gold.

Early bearers of the name.

The name appears in Florentine chronicles as early as the close of the 12th century, although only casually mentioned in connexion with various offices of the republic. The first of the family to be a distinct figure in history was Salvestro dei Medici, who, in the year 1378, took an active part in the revolt of the Ciompi—so-called because it was led by a wool-carder (*ciompo*), one Michele di Lando, and because the chief share in it was taken by the populace, who held the reins of government for some time, and sought to obtain extended political rights. But, although Michele di Lando was the nominal chief of the revolt, Salvestro dei Medici was its real leader. The latter, although a member of the greater guilds, had joined the lesser and sought to be at their head, in order to lay the foundation of his own power and that of his kindred by attacking the Albizzi, who were the leading men of the greater guilds. The victory of the Ciompi, however, was brief, for the excesses of the lower classes brought about a reaction, in which they were crushed, and Michele di Lando sent into banishment. Nevertheless the lesser guilds had gained some ground by this riot, and Salvestro dei Medici the great popularity at which he had aimed. His policy during that period had traced the sole possible road to power in liberty-loving Florence. And this was the road henceforth pursued by the Medici.

Salvestro.

On Salvestro's death in 1388 the Albizzi repossessed themselves of the government, and conducted the wars of the republic. Vieri dei Medici, who seems to have been the next head of the family, understanding the temper of

the times, abstained from becoming a popular leader, and left it to his successors to prosecute the task under easier conditions. Then, in the person of Giovanni, son of Bicci dei Medici (1360–1429), another branch of the family arose, and became from that time forward its representative branch. Indeed this Giovanni may be considered the actual founder of Medicean greatness. He took little part in political affairs, but realized an immense fortune by trade,—establishing banks in Italy and abroad, which in his successors' hands became the most efficient engines of political power. The council of Constance (1414–1418) enabled Giovanni dei Medici to realize enormous profits. Besides, like his ancestor Salvestro, he was a constant supporter of the lesser guilds in Florence. Historians record his frequent resistance to the Albizzi when they sought to oppress the people with heavier taxation, and his endeavours to cause the chief weight to fall upon the richer classes. For this reason he was in favour of the so-called law of *catasto*, which, by assessing the property of every citizen, prevented those in power from arbitrarily imposing taxes that unjustly burdened the people. In this way, and by liberal loans of money to all who were in need of it, he gained a reputation that was practically the foundation-stone of the grand family edifice. Giovanni dei Medici died in 1429 leaving two sons, Cosimo (1389–1464) and Lorenzo (1395–1440). From the former proceeded the branch that held absolute sway for many generations over the nominal republic of Florence, and gave to Italy popes like Leo X. and Clement VII. On the extinction of this elder line in the 16th century, the younger branch derived from Lorenzo, Cosimo's brother, seemed to acquire new life, and for two centuries supplied grand-dukes to Tuscany. Cosimo, surnamed Cosimo the Elder, to distinguish him from the many others bearing the same name, and honoured after his death by the title of *Pater patriæ*, first succeeded in solving the strange problem of becoming absolute ruler of a republic that was keenly jealous of its liberty, without holding any fixed office, without suppressing any previous form of government, and always preserving the appearance and demeanour of a private citizen. Born in 1389, he had already reached the age of forty at the time of his father's death. He had a certain amount of literary culture, and throughout his life showed much taste and an earnest love both for letters and art. But his father had mainly trained him to commerce, for which he had a special liking and aptitude. In fact he was devoted to business to the day of his death, and like his forefathers derived pecuniary advantage from his friendly relations with the papal court. He accompanied Pope John XXIII. to the council of Constance, transacted a vast amount of business in that city, and made very large gains. He then travelled in Germany, and after his return to Florence discharged several ambassadorial missions. At the death of his father he was possessed of a vast fortune and an extended experience, and inherited the leadership of the opposition to the then dominant party of the greater guilds headed by Rinaldo degli Albizzi, Palla Strozzi, and Niccolò da Uzzano. Of gentle and kindly manners, generous in lending and even in giving money whenever he could gain popularity by that means, at critical moments he frequently came to the succour of the Government itself. He was very dexterous in turning his private liberalities to account for the increase of his political prestige, and showed no less acumen and still fewer scruples in making use of his political prestige for purposes of pecuniary profit. Indeed, whenever his own interests were at stake, he showed himself capable of positive villainy, although this was always tempered by calculation. Cosimo proved his skill in these knavish arts during the war between Florence and Lucca. He had joined the Albizzi in urging on this war, and many writers assert that he turned it to much pecuniary advantage by means of loans to the Government and other banking operations. When, however, military affairs went badly, Cosimo joined the discontented populace in invectives against the war and those who had conducted it. This won him an enormous increase of popularity, but the hatred of the Albizzi and their friends augmented in equal degree, and a conflict became inevitable. The Albizzi, who were far more impetuous and impatient than Cosimo, were now bent upon revenge. In 1433 one of their own friends, Bernardo Guadagni, was elected gonfalonier, and thereupon Cosimo dei Medici was called to the palace and summarily imprisoned in the tower. A general assembly of the people was convoked and a "balía" chosen, which changed the Government and sent Cosimo into exile. Undoubtedly the Albizzi party would have preferred a heavier sentence, but they did not dare to attempt their enemy's life, being well aware of the great number of his adherents. Cosimo had some apprehension that he might be poisoned in prison, but Federigo dei Malavolti, captain of the palace guard, showed him the utmost kindness, and, in order to soothe his fears, voluntarily shared his meals. On the 3d October the prisoner was sent to Padua, his allotted place of exile.

Giovanni.

Cosimo the Elder.

The Albizzi speedily saw that they had done either too much or too little. While seeking to keep the government entirely in their own hands, they beheld the continual growth of the Medici party. When it was necessary to make a campaign in Romagna against the mercenary captains commanding the forces of the duke of Milan, it was plainly seen that in banishing Cosimo the republic had lost the only citizen banker in a position to assist it with considerable loans. The Florentines were defeated by Piccinino in 1434, and this event greatly increased the public exasperation against the Albizzi. Meanwhile Cosimo, who had gone to Padua as a private individual, was entertained there like a prince. Then, being permitted to transfer his residence to Venice, he entered on a course of lavish expenditure. He was overwhelmed with letters and appeals from Florence. Finally, on the 1st of September 1434, a signory was elected composed of his friends, and his recall was decreed. Rinaldo degli Albizzi determined to oppose it by force, and rushed to the Piazza with a band of armed men; but his attempt failed, and he left the country to return no more. The Medici were now reinstated in all their former dignities and honours, and Cosimo, on the evening of September 6th, rode past the deserted mansions of the Albizzi and re-entered his own dwelling after an exile of a year. For three centuries, dating from that moment, the whole history of Florence was connected with that of the house of Medici.

Cosimo's first thought was to secure himself against all future risk of removal from Florence, and accordingly he drove the most powerful citizens into exile to all parts of Italy. Nor did he spare even his former political adversary, Palla Strozzi, although the latter had been favourable to him during the recent changes. His rigour in this particular case was universally censured, but Cosimo would tolerate no rivals in the city, and was resolved to abase the great families and establish his power by the support of the lower classes. He was accustomed to say that states could not be ruled by paternosters. Still, when cruelty seemed requisite, he always contrived that the chief odium of it should fall upon others. When Neri Capponi, the valiant soldier and able diplomatist, gained great public favour by his military prowess, and his influence was further increased by the friendship of Baldaccio d'Anghiari, captain of the infantry, Cosimo resolved to weaken his position by indirect means. Accordingly, when in 1441 a partisan of the Medici was elected gonfalonier, Baldaccio was instantly summoned to the palace, imprisoned,

murdered, and his body hurled from the window. No one could actually fix this crime upon Cosimo, but the majority believed that he had thus contrived to rid himself of one enemy and cripple another without showing his hand. It was impossible for Cosimo openly to assume the position of tyrant of Florence, nor was it worth his while to become gonfalonier, since the term of office only lasted two months. It was necessary to discover some other way without resorting to violence; he accordingly employed what were then designated "civil methods." He managed to attain his object by means of the "balie." These magistracies, which were generally renewed every five years, placed in the ballot bags the names of the candidates from whom the signory and other chief magistrates were to be chosen. As soon as a "balia" favourable to Cosimo was formed, he was assured for five years of having the government in the hands of men devoted to his interests. He had comprehended that the art of politics depended rather upon individuals than institutions, and that he who ruled men could also dictate laws. His foreign policy was no less astute. His great wealth enabled him to supply money not only to private individuals, but even to foreign potentates. Philippe de Comines tells us that Cosimo frequently furnished Edward IV. of England with sums amounting to many hundred thousand florins. When Tommaso Parentucelli was still a cardinal, and in needy circumstances, Cosimo made him considerable loans without demanding guarantees of payment. On the cardinal's accession to the tiara as Nicholas V. he was naturally very well disposed towards Cosimo, and employed the Medici bank in Rome in all the affairs of the curia, which brought immense profits to the house. At the time when Francesco Sforza was striving for the lordship of Milan, Cosimo foresaw his approaching triumph, showed him great friendship, and aided him with large sums of money. Accordingly, when Sforza became lord of Milan, Cosimo's power was doubled. Without the title of prince, this merchant showed royal generosity in his expenditure for the promotion of letters and the fine arts. Numerous edifices were raised and public works accomplished with his purse. Besides his palace in the city, he constructed noble villas at Careggi, Fiesole, and other places. He built the basilica of Fiesole, and that of St Lorenzo in Florence, and enlarged the church and monastery of St Mark. Even in distant Jerusalem he endowed a hospice for the use of pilgrims. The artists of the day comprised men like Donatello, Brunelleschi, Ghiberti, Luca della Robbia, and many others, and Cosimo's magnificent commissions not only developed their powers but stimulated other men of wealth to the patronage of art. Without being a scholar, Cosimo had a genuine taste for letters, and gave them much and efficient patronage. He purchased many Greek and Latin manuscripts; he opened the first public library at St Mark's at his own expense, and founded another in the abbey of Fiesole. The Greek refugees from Constantinople found a constant welcome in his palace. During the council of Florence (1439–1442), Gemisthus Pletho spoke to him with enthusiasm of the Platonic philosophy. Cosimo was so deeply attracted by the theme that he decided to have the young Marsilio Ficino trained in philosophy and Greek learning in order to make a Latin translation of the complete works of Plato. And thus a version was produced that is still considered one of the best extant, and that Platonic academy was founded which led to such important results in the history of Italian philosophy and letters. On the 1st of August 1464 Cosimo breathed his last, at the age of seventy-five, while engaged in listening to one of Plato's dialogues.

The concluding years of his life had been years of little happiness for Florence. Being old and infirm, he had left the government to the management of his friends, among whom Luca Pitti was one of the more powerful, and they had ruled with disorder, corruption, and cruelty. The lordship of Florence accordingly did not pass without some difficulty and danger into the hands of Piero, surnamed the Gouty, Cosimo's only surviving legitimate son. Afflicted by gout, and so terribly crippled that he was often only able to use his tongue, the new ruler soon discovered that a plot was on foot to overthrow his power. However showing far more courage than he was supposed to possess, he had himself borne on a litter from his villa to Florence, defeated his enemies' designs, and firmly re-established his authority. But his success may be mainly attributed to the enormous prestige bequeathed by Cosimo to his posterity. Piero died at the end of five years' reign, on the 3d December 1469, leaving two sons, Lorenzo (1449–92) and Giuliano (1453–78). The younger, the gentler and less ambitious of the pair, was, as we shall presently see, quickly removed from the world. Lorenzo, on the contrary, at once seized the reins of state with a firm grasp, and was, chronologically, the second of the great men bestowed upon Italy by the house of Medici. In literary talent he was immensely superior to Cosimo, but greatly his inferior in the conduct of the commercial affairs of the house, for which he had neither aptitude nor inclination. In politics he had nobler conceptions and higher ambitions, but he was more easily carried away by his passions, less prudent in his revenge, and more disposed to tyranny. He had studied letters from his earliest years under the guidance of Ficino and other leading literati of the day, who were constant habitués of the Medici palace. At the age of eighteen he visited the different courts of Italy in order to gain experience of the world and mankind. At his father's death he was only twenty-one years old, but instantly showed his determination to govern Florence with greater despotism than his father or grandfather. He speedily resorted to the system of the "balie," and was very dexterous in causing the first to be chosen to suit his purpose. He then proceeded to humiliate the great families and exalt those of little account, and this was the policy he constantly pursued. His younger brother Giuliano, being of a mild and yielding disposition, had only a nominal share in the government.

Piero the Gouty.

Lorenzo the Magnificent.

Lorenzo's policy was not exempt from danger, but, although prosecuted with less caution, it was still the old astute and fortunate policy initiated by Cosimo. But the grandson bestowed no care upon his commercial interests, although squandering his fortune with far greater lavishness. Accordingly he was sometimes driven to help himself from the public purse without ever being able to assist it as Cosimo had done. All this excited blame and enmity against him, while his greed in the matter of the alum mines of Volterra, and the subsequent sack of that unhappy city, were crimes for which there was no excuse. Among his worst enemies were the Pazzi, and, as they formed a very powerful clan, he sought their ruin by competing with them even in business transactions. They were just on the point of inheriting the large property of Giovanni Borromeo when, in order to prevent this, Lorenzo hurriedly caused a law to be passed that altered the right of succession. The hatred of the Pazzi was thereby exasperated to fury. And in addition to these things there ensued a desperate quarrel with Pope Sixtus IV., a man of very impetuous temper, who, on endeavouring to erect a state on the frontiers of the Florentine republic for the benefit of his nephews, found a determined and successful opponent in Lorenzo. Consequently the Pazzi and Archbishop Salviati, another enemy of Lorenzo, aided by the nephews of the pontiff, who was himself acquainted with the whole matter, determined to put an end to the family.

On the 26th April 1478, while Giuliano and Lorenzo were attending high mass in the cathedral of Florence, the former was mortally stabbed by conspirators, but the latter was able to beat back his assailants and escape into the sacristy. His life saved; and, no longer having to share the government with a brother, Lorenzo profited by the opportunity to wreak cruel vengeance upon his foes. Several of the Pazzi and their followers were hanged from the palace windows; others were hacked to pieces, dragged through the streets, and cast into the Arno, while a great many more were condemned to death or sent into exile. Lorenzo seemed willing and able to become a tyrant. But he stopped short of this point. He knew the temper of the city, and had also to look to fresh dangers threatening him from without. The pope had excommunicated him, put Florence under an interdict, and, being seconded by the Neapolitan king, made furious war against the republic. These hostilities speedily assumed alarming proportions, and the Florentines began to tire of submitting to so many hardships in order to support the yoke of a fellow-citizen. Lorenzo's hold over Florence seemed endangered. But he did not lose heart, and, on the contrary, rose superior to the difficulties by which he was encompassed. He boldly journeyed to Naples, to the court of King Ferdinand of Aragon, who was reputed to be as treacherous as he was cruel, and succeeded in obtaining from him an honourable peace, that soon led to a reconciliation with Sixtus. Thus at last Lorenzo found himself complete master of Florence, and was in a position to turn his power to account. But, as the "balíe" changed every five years, it was always requisite, in order to retain his supremacy, that he should be prepared to renew the usual manœuvre at the close of that term and have another elected equally favourable to his aims. This was often a difficult achievement, and Lorenzo showed much dexterity in overcoming all obstacles. In 1480 he compassed the institution of a new council of seventy, which was practically a permanent "balía" with extended powers, inasmuch as it not only elected the chief magistrates, but had also the administration of numerous state affairs. But, this permanent council of his own devoted adherents once formed, his security was firmly established. By this means, the chroniclers tell us, "liberty was buried," but the chief affairs of the state were always conducted by intelligent and experienced men, who promoted the public prosperity. Florence was still called a republic; the old institutions were still preserved, if only in name. Lorenzo was absolute lord of all, and virtually a tyrant. His immorality was scandalous; he kept an army of spies, and frequently meddled in the citizens' most private affairs, and exalted men of the lowest condition to important offices of the state. Yet, as Guicciardini remarks, "if Florence was to have a tyrant, she could never have found a better or more pleasant one." In fact all industry, commerce, and public works made enormous progress. The civil equality of modern states, which was quite unknown to the Middle Ages, was more developed in Florence than in any other city of the world. Even the condition of the peasantry was far more prosperous than elsewhere. And Lorenzo's authority was not confined to Tuscany, but was also very great throughout the whole of Italy. He was on the friendliest terms with Pope Innocent VIII., from whom he obtained the exaltation of his son Giovanni to the cardinalate at the age of fourteen. This boy cardinal was afterwards Pope Leo X. From the moment of the decease of Sixtus IV., the union of Florence and Rome became the basis of Lorenzo's foreign policy. By its means he was able to prevent the hatreds and jealousies of the Sforzas of Milan and the Aragonese of Naples from bursting into the open conflict that long threatened, and after his death actually caused, the beginning of new and irreparable calamities. Hence Lorenzo was styled the needle of the Italian compass.

But the events we have narrated cannot suffice for the full comprehension of this complex character, unless we add the record of his deeds as a patron of letters and his achievements as a writer. His palace was the school and resort of illustrious men. Within its walls were trained the two young Medici afterwards known to the world as Leo X. and Clement VII. Ficino, Poliziano, Pico della Mirandola, and all members of the Platonic academy were its constant habitués. It was here that Pulci gave readings of his *Morgante*, and Michelangelo essayed the first strokes of his chisel. Lorenzo's intellectual powers were of exceptional strength and versatility. He could speak with equal fluency on painting, sculpture, music, philosophy, and poetry. But his crowning superiority over every other Mæcenas known to history lay in his active participation in the intellectual labours that he promoted. Indeed at certain moments he was positively the leading spirit among the literati of his time. He was an elegant prose writer, and was likewise a poet of real originality. At that period Italians were forsaking erudition in order to forward the revival of the national literature by recurring to the primitive sources of the spoken tongue and popular verse. It is Lorenzo's lasting glory to have been the initiator of this movement. Without being—as some have maintained—a poet of genius, he was certainly a writer of much finish and eloquence, and one of the first to raise popular poetry to the dignity of art. In his *Ambra*, his *Caccia del Falcone*, and his *Nencia da Barberino*, he gives descriptions of nature and of the rural life that he loved, with the graphic power of an acute and tasteful observer, joined to an ease of style that occasionally sins by excess of homeliness. Both in his art and in his politics he leant upon the people. The more oppressive his government, the more did he seek in his verses to incite the public to festivities and lull it to slumber by sensual enjoyments. In his *Ballate*, or songs for dancing, and more especially in his carnival songs, a kind of verse invented by himself, Lorenzo displayed all the best qualities and worst defects of his muse. Marvellously and spontaneously elegant, very truthful and fresh in style, fertile in fancy and rich in colour, they are often of a most revolting indecency. And these compositions of one filling a princely station in the city were often sung by their author in the public streets, in the midst of the populace.

Lorenzo left three sons,—Pietro (1471–1503), Giovanni (1475–1521), and Giuliano (1479–1516). He was succeeded by Pietro, whose rule lasted but for two years. During this brief term he performed no good deeds, and only displayed inordinate vanity and frivolity. His conduct greatly helped to foment the hatred between Lodovico Sforza and Ferdinand of Naples, which hastened the coming of the French under Charles VIII., and the renewal of foreign invasions. No sooner did the French approach the frontiers of Tuscany than Pietro, crazed with fear, hastened to meet them, and, basely yielding to every demand, accepted terms equally humiliating to himself and the state. But, returning to Florence, he found that the enraged citizens had already decreed his deposition, in order to reconstitute the republic, and was therefore compelled to escape to Venice. His various plots to reinstate himself in Florence were all unsuccessful. At last he went to the south of Italy with the French, was drowned at the passage of the Garigliano in 1503, and was buried in the cloister of Monte Cassino.

The ensuing period was adverse to the Medici, for a republican government was maintained in Florence from 1494 to 1512, and the city remained faithful to its alliance with the French, who were all-powerful in Italy. Cardinal

Giovanni, the head of the family, resided in Rome, playing the patron to a circle of literati, artists, and friends, seeking to increase his popularity, and calmly waiting for better days. The battle of Ravenna wrought the downfall of the fortunes of France in Italy, and led to the rise of those of Spain, whose troops entered Florence to destroy the republic and reinstate the Medici. Pietro had now been dead for some time, leaving a young son, Lorenzo (1492–1519), who was afterwards duke of Urbino. The following year (1513) Cardinal Giovanni was elected pope, and assumed the name of Leo X. He accordingly removed to Rome, leaving his brother Giuliano with his nephew Lorenzo in Florence, and accompanied by his cousin Giulio, who was a natural son of the Giuliano murdered in the conspiracy of the Pazzi, and was soon destined to be a cardinal and ultimately a pope. Meanwhile his kinsmen in Florence continued to govern that city by means of a "balía," although preserving an empty show of republican institutions. And thus, being masters of the whole of central Italy, the Medici enjoyed great authority throughout the country, and their ambition plumed itself for still higher flights. This was the moment when Niccolò Machiavelli, in his treatise *The Prince*, counselled them to accomplish the unity of Italy by arming the whole country, and expelling its foregin invaders.

Leo X., who is only indirectly connected with the history of Florence, gave his name to the age in which he lived in consequence of his magnificent patronage of art and letters in Rome. But he was merely a clever amateur, and had not the literary gifts of his father Lorenzo. He surrounded himself with versifiers and inferior writers, who enlivened his board and accompanied him wherever he went. He liked to lead a gay and untroubled life, was fond of theatrical performances, satires, and other intellectual diversions. His patronage of the fine arts, his genuine affection for Raphael, and the numerous works he caused to be executed by him and other artists, have served to confer an exaggerated glory on his name. He failed to comprehend the significance of the great religious movement already stirring in Germany, and had not the remotest idea of the grave importance of the Reformation, which indeed he unconsciously promoted by his reckless and shameless sale of indulgences. The whole policy of Pope Leo X. consisted in oscillating between France and Spain, in always playing fast and loose, and deceiving both powers in turn. Yet the evil results of this contemptible policy never seemed to disturb his mind. He finally joined the side of the emperor Charles V., and in 1521, at the time of the defeat of the French by the Spanish troops on the river Adda, he ceased to breathe at his favourite villa of Magliana. Giuliano dei Medici had died during Leo's reign, in 1516, without having ever done anything worthy of record. He was the husband of Philiberta of Savoy, was duke of Nemours, and left a natural son, Ippolito dei Medici (1511–1535), who afterwards became a cardinal. Lorenzo, being of more ambitious temper, was by no means content to remain at the head of the Florence Government hampered by many restrictions imposed by republican institutions, and subject to the incessant control of the pope. In his eagerness to aggrandize his kinsmen, the latter had further decided to give Lorenzo the duchy of Urbino, and formally invested him in its rights, after expelling on false pretences its legitimate lord, Francesco Maria della Rovere. This prince, however, soon returned to Urbino, where he was joyously welcomed by his subjects, and Lorenzo regained possession only by a war of several months, in which he was wounded. In 1519 he also died, worn out by disease and excess. By his marriage with Madeleine de la Tour d'Auvergne, he had one daughter, Caterina dei Medici (1519–89), married in 1533 to Henry, duke of Orleans, afterwards king of France. She played a long and sinister part in the history of that country. Lorenzo also left a natural son named Alessandro, inheriting the frizzled hair and projecting lips of the negro or mulatto slave who had given him birth. His miserable death will be presently related. Thus the only three surviving representatives of the chief branch of the Medici, Cardinal Giulio, Ippolito, and Alessandro were all of illegitimate birth, and left no legitimate heirs.

Cardinal Giulio, who had laboured successfully for the reinstatement of his family in Florence in 1512, had been long attached to the person of Leo X. as his trusted factotum and companion. He had been generally regarded as the mentor of the pope, who had no liking for hard work. But in fact, his frivolity notwithstanding, Leo X. always followed his own inclinations. He had much aptitude for command, and pursued his shuffling policy without any mental anxiety. Giulio, on the contrary, shrank from all responsibility, muddled his brains in weighing the reasons for and against every possible decision, and was therefore a better tool of government in others' hands than he was fit to govern on his own account. When Giuliano and Lorenzo died, the pope appointed the cardinal to the government of Florence. In that post, restricted within the limits imposed by republican institutions, and acting under the continual direction of Rome, he performed his duties fairly well. He caressed the citizens with hopes of extended liberties, which, although never destined to be fulfilled, long served to keep men's minds in a pleasant flutter of expectation; and when the more impatient spirits attempted to raise a rebellion he speedily quenched it in blood. When, after the death of Leo X. and the very brief pontificate of Adrian VI., he was elected pope (1523) under the name of Clement VII., he entrusted the government of Florence to Cardinal Silvio Passerini conjointly with Alessandro and Ippolito, who were still too young to do much on their own account.

The pontificate of Leo X. had been a time of felicity to himself if of disaster to Italy and the church. The reign of Clement, on the contrary, was fatal to himself as well, a result chiefly due to his hesitating temper and continual uncertainty of mind. His policy, like that of Leo X., consisted in perpetual oscillation between France and Spain. By his endeavours to trick all the world, he frequently ended in being tricked himself. In 1525 he was the ally of the French, who then suffered a terrible defeat at Pavia, where their king Francis I. was taken prisoner. The armies of Charles V. triumphantly advanced, without Clement being able to oppose any effectual resistance. Both Rome and Florence were threatened with a fearful catastrophe.

Giovanni delle Bande Nere.

Thus far we have had no occasion to speak of the younger branch of the Medici, descended from Lorenzo, brother to Cosimo the Elder. Always in obscurity, and always held in check by the elder line, it now seemed to acquire new life, and first entered the arena of history when the other was on the point of extinction. In fact the most valiant captain of the papal forces was Giovanni dei Medici, afterwards known by the name of Giovanni delle Bande Nere. His father was Giovanni, son of Pier Francesco, who was the son of Lorenzo, the brother of Cosimo dei Medici. History has little to tell of the elder Giovanni; but his wife Caterina Sforza, of whom he was the third husband, was a woman of more than masculine vigour. Giovanni dei Medici married her in 1497, but died in 1498, leaving her with one son who was christened Lodovico, but afterwards took his father's name of Giovanni (1498–1526). Trained to arms from his earliest years, this youth inherited all the energy of his mother, whose Sforza blood seemed to infuse new life into the

younger branch of the Medici. Notwithstanding his extreme youth, he had already achieved the title of the best captain in Italy. He always fought with immense dash and daring, and was devotedly loved and obeyed by his soldiery. He was the only leader who opposed a determined resistance to the imperial forces. He was seriously wounded at Pavia when fighting on the French side. On his recovery he joined the army of the League, and was much enraged by finding that the duke of Urbino, commander of the Venetian and papal forces, would never decide on attacking. When the imperial troops were struggling through the marshes of Mantua, surrounded on every side, and without stores or ammunition, Giovanni could not resign himself to inactivity like his colleagues in command. He was ignorant that the imperialists had just received supplies and artillery from the duke of Ferrara, and therefore daringly attacked them with a small body of men without taking any precautions for defence. One of the first shots fired by the enemy injured him so fatally that he died a few days after. He was married to Maria Salviati, by whom he had one son, Cosimo (1519–1574), born, as we shall see, to lofty fortunes, for he became the first grand-duke of Tuscany, and indeed the founder of the grand-duchy and the new dynasty.

Meanwhile the imperial army pursued its march upon Rome, captured the Eternal City after a few hours' combat, and cruelly sacked it during many days (1527). Thanks to his perpetual shuffling and excessive avarice, the pope found himself utterly forsaken, and, being unable to defend the city, was obliged to seek refuge in the castle of St Angelo, whence he only effected his escape after some months. He then signed a treaty of alliance with the emperor (1529), who sent an army to besiege Florence and restore the Medici, whom the people had expelled in 1527 on the re-establishment of the republic. After an heroic defence, the city was forced to surrender (1530); and, although it was expressly stipulated that the ancient liberties of Florence should be respected, every one foresaw that the conditions would be violated. In fact, pope and emperor immediately began to dispute as to which should be the new lord of the city. Clement VII. had inherited the traditional family dislike for the younger branch of his kin, and so the choice lay between the two bastards Ippolito and Alessandro. The former being a cardinal, the latter was chosen. Alessandro, who already bore the title of duke of Città di Penna, came to Florence in 1531, and by imperial patent was nominated head of the republic. According to the terms of this patent, the former liberty enjoyed under the Medicean rule was to remain intact. But no previous ruler of the city had enjoyed hereditary power confirmed by imperial patent, and such power was incompatible with the existence of a republic. Moreover, Clement VII. showed dissatisfaction with the uncertainty of the power conferred upon his kinsman, and finally succeeded in obtaining additional privileges. On the 4th of April 1532 a parliament was convoked for the last time in Florence, and, as usual, approved every measure proposed for acceptance. Accordingly a new council was formed of two hundred citizens elected for life, forty-eight of which number were to constitute a senate. Alessandro, as duke of the republic, filled the post of gonfalonier, and carried on the government with the assistance of three senators, changed every three months, who took the place of the suppressed signory.

Duke Alessandro.

The duke's chief advisers, and the contrivers of all these arrangements, were Baccio Valori, Francesco Vettori, and above all Francesco Guicciardini,—men, especially the two latter, of lofty political gifts and extensive influence. The mind and character of Duke Alessandro were as yet comparatively unknown. At first he seemed very anxious to win the favour of the people, and disposed to rule with justice and prudence. But soon encountering difficulties that he was unable to overcome, he began to neglect the business of the state, treated his new office as affording the means for increased indulgence in pleasure and vice, and acted as if the sole function of government consisted in lulling the people by festivities and corrupting it by the dissolute life of which he set the example. The question of the moment was the transformation of the old republican régime into a princedom; as an unavoidable result of this change it followed that Florence was no longer to be the ruling city to whose inhabitants alone belonged the monopoly of political office. When the leading Florentine families realized, not only that the republic was destroyed, but that they were reduced to equality with those whom they had hitherto regarded as their inferiors and subjects, their rage was indescribable, and hardly a day passed without the departure of influential citizens who were resolved to achieve the overthrow of their new ruler. They found a leader in Cardinal Ippolito dei Medici, who was then in Rome, embittered by the preference given to Alessandro, and anxious to become his successor with the least possible delay. Under the pressure of terror the duke at once became a tyrant. He garrisoned the different cities, and began the erection in Florence of the Fortezza da Basso, built chiefly at the expense of Filippo Strozzi, who afterwards met his death within its walls.

Cardinal Ippolito

In 1534 Clement VII. died, and the election fell on Paul III., from whom Cardinal Ippolito hoped to obtain assistance for his designs. Accordingly the principal Florentine exiles were despatched on a mission to the emperor Charles V. with complaints of Alessandro's tyranny and his shameless violation of the terms upon which the city had surrendered. Cardinal Ippolito also represented his own willingness to carry on the government of Florence in a more equitable manner, and promised the emperor a large sum of money. Reply being delayed by the emperor's absence, he became so impatient that he set out, accompanied by several exiles, to meet Charles in Tunis, but on the 10th of August 1535 died suddenly by the way, at Itri, poisoned by order of Alessandro. Such at least was the general belief, and it was confirmed by the same fate befalling other enemies of the duke about the same time. On the emperor's return from Africa, the exiles presented themselves to him in Naples, and the venerable patriot Jacopo Nardi pleaded their cause. Duke Alessandro, being cited to appear, came to Naples accompanied by Francesco Guicciardini, who by speaking in his defence rendered himself odious to all friends of liberty, and irretrievably tarnished his illustrious name. The cardinal being dead, it was hard to find a successor to Alessandro. On this account, and perhaps to some extent through the emperor's personal liking for the duke, the latter rose higher than before in the imperial favour, married Margaret of Austria, the natural daughter of Charles, and returned to Florence with increased power. And now Alessandro indulged unchecked in the lowest excesses of tyranny, and although so recently a bridegroom gave way to increased libertinism. His whole time was passed in vicious haunts and in scandalous adventures. In order to conceal the obscurity of his birth, he left his mother to starve, and it was even asserted that he finally got rid of her by poison.

His constant associate in this disgraceful routine was his distant kinsman Lorenzo, generally known as Lorenzino dei Medici. Of the younger branch of the Medici, the latter was second cousin of the Cosimo already mentioned as the son of Giovanni delle Bande Nere. He had much culture and literary talent, but led an irregular life, sometimes acting like a madman and sometimes like a

Lorenzino dei Medici.

villain. He was a writer of considerable elegance, the author of several plays, one of which, the *Aridosio*, was held to be among the best of the age, and he was a worshipper of antiquity. Notwithstanding these tastes, when in Rome he knocked off the heads of some of the finest statues of the age of Adrian, an act by which Clement VII. was so incensed that he threatened to have him hanged. Thereupon Lorenzino fled to Florence, where he became the friend of Duke Alessandro and his partner in the most licentious excesses. They went together to houses of ill-fame, and violated private dwellings and convents. They often showed themselves in public mounted on the same horse. All Florence eyed them with disgust, but no one foresaw the tragedy that was soon to take place.

Assassination of Alessandro.

On the evening of January 5th, 1537, after a day passed in the usual excesses, Lorenzino led the duke to his own lodging, and left him there, promising shortly to return with the wife of Leonardo Ginori. Alessandro, worn out by the exertions of the day, fell asleep on the couch while awaiting Lorenzino's return. Before long the latter came accompanied by a desperado known as the Scoronconcolo, who aided him in falling on the sleeper. Roused by their first thrusts, the duke fought for his life, and was only despatched after a violent struggle. The murderers then lifted the body into bed, hid it beneath the clothes, and, Lorenzino having attached a paper to it bearing the words, *vincit amor patriæ, laudumque immensa cupido*, they both fled to Venice. In that city Lorenzino was assassinated some ten years later, in 1548, at the age of thirty-two, by order of Alessandro's successor. Thus he was only about twenty-two at the time he committed the murder. He wrote an *Apologia*, in which he defended himself with great skill and eloquence, saying that he had been urged to the deed solely by love of liberty. For this reason alone he had followed the example of Brutus and played the part of friend and courtier. The tone of this *Apologia* is so straightforward, sometimes even so eloquent and lofty, that we should be tempted to give it credence were it possible to believe the assertions of one who not only by his crime but by the infamy of his previous and subsequent career completely gave the lie to his vaunted nobility of purpose. By Alessandro's death the elder branch of the Medici became extinct, and thus the appearance of the younger line was heralded by a bloody crime.

When the duke's absence from his own palace was discovered on the morning of January 6th, he was at first supposed to have spent the night with one of his mistresses; but soon, some alarm being felt, search was made, and Cardinal Cybo was the first to discover the murder. Enjoining the strictest secrecy, he kept the corpse concealed for three days, and then had it interred in the sacristy of San Lorenzo. Meanwhile he had hastily summoned Alessandro Vitelli and the other captains, so that, by the time Alessandro's death was made public, the city was already filled with troops. The cardinal then convoked the council of forty-eight to decide upon a successor. Alessandro's only issue was a natural son named Giulio, aged five. The cardinal favoured his election, in the hope of keeping the real sovereignty in his own hands. But he speedily saw the impossibility of carrying out a design that was ridiculed by all. On the other hand, Guicciardini, Vettori, and others of the leading citizens favoured the choice of Cosimo, the son of Giovanni delle Bande Nere. He was already in Florence, was aged seventeen, was keen-witted and aspiring, strong and handsome in person, heir to the enormous wealth of the Medici, and, by the terms of the imperial patent, was Alessandro's lawful successor. Charles V. approved the nomination of Cosimo, who without delay seized the reins of government with a firm grasp. Like Alessandro, he was named head of the republic; and Guicciardini and others who had worked hardest in his cause hoped to direct him and keep him under their control. But Cosimo soon undeceived them by proving that, his youth notwithstanding, he had a will of his own, and was resolved to rule unshackled by republican forms and unhampered by advisers disposed to act as mentors. The Florentines had now an absolute prince who was likewise a statesman of eminent ability.

Cosimo I.

On learning the death of Alessandro and the election of Cosimo, the exiles appreciated the necessity for prompt action, as all delay would be fatal to the overthrow of the Medicean rule. They had received money and promises from France; they were strengthened by the adhesion of Filippo Strozzi and Baccio Valori, who had both become hostile to the Medici through the infamous conduct and mad tyranny of Alessandro; and Strozzi brought them the help of his enormous fortune and the prowess of that very distinguished captain, his son Piero. The exiles accordingly met, and assembled their forces at Mirandola. They had about four thousand infantry and three hundred horse; among them were members of all the principal Florentine families; and their leaders were Bernardo Salviati and Piero Strozzi. They marched rapidly, and entered Tuscany towards the end of July 1537. Cosimo on this occasion displayed signal capacity and presence of mind. Fully informed of the exiles' movements by means of his spies, he no sooner learned their approach than he ordered Alessandro Vitelli to collect the best German, Spanish, and Italian infantry at his disposal, and advance against the enemy without delay. On the evening of July 31 Vitelli marched towards Prato with seven hundred picked infantry and a band of one hundred horse, and on the way fell in with other Spanish foot soldiers who joined the expedition. At early dawn the following morning he made a sudden attack on the exiles' advanced guard close to Montemurlo, an old fortress converted into a villa belonging to the Nerli. Having utterly routed them, he proceeded to storm Montemurlo, where Filippo Strozzi and a few of his young comrades had taken refuge and barricaded the gates. Knowing that they must either conquer or die, they made a desperate resistance for some hours, and then, overwhelmed by superior numbers, were obliged to yield themselves prisoners. The main body of the army was still at some distance, having been detained in the mountains by heavy rains and difficult passes, and, on learning the defeat at Montemurlo, its leader refused to advance, and turned back by the way he had come. Alessandro Vitelli then re-entered Florence with his victorious army and his fettered captives. Cosimo had achieved his first triumph.

All the prisoners, who were members of great families, were brought before Cosimo, and were received by him with courteous coldness. Soon, however, a scaffold was erected in the Piazza, and on four mornings in succession four of the prisoners were beheaded. Then the duke saw fit to stay the executions. Baccio Valori, however, and his son and nephew were beheaded on the 20th of August in the courtyard of the Bargello. Filippo Strozzi still survived, confined in the Fortezza da Basso, that had been built at his expense. His family was illustrious, he had numerous adherents, and he enjoyed the protection of the French king. Nevertheless Cosimo only awaited some plausible pretext to rid himself of this dreaded enemy. He brought him to trial and had him put to the question. But this cruelty led to nothing, for Strozzi denied every accusation and bore the torture with much fortitude. On December 18th he was found dead in his prison, with a blood-stained sword by his side, and a slip of paper bearing these words: *exoriare aliquis nostris ex ossibus ultor*. It was believed that, having renounced all hope of his life being spared, Strozzi had preferred suicide to death at the hands of the

executioner. Some, however, thought that Cosimo had caused him to be murdered, and adopted this mode of concealing the crime. The young prince's cold-blooded massacre of his captives cast an enduring shadow upon his reign and dynasty. But it was henceforward plain to all that he was a man of stern resolve, who went straight to his end without scruples or half measures. Before long he was regarded by many as the incarnation of Machiavelli's *Prince*, "inasmuch as he joined daring to talent and prudence, was capable of great cruelty, and yet could practise mercy in due season." Guicciardini, who still pretended to act as mentor, and who on account of his many services had a certain influence over him, was obliged to withdraw from public life and busy himself with writing his *History* at his villa of Arcetri. He died in this retreat in 1540, and it was immediately rumoured that the duke had caused him to be poisoned. This shows the estimation in which Cosimo was now held. It was true that he punished with death all who dared to resist his will. By 1540 sentence of death had been pronounced against four hundred and thirty contumacious fugitives, and during his reign one hundred and forty men and six women actually ascended the scaffold, without counting those who perished in foreign lands by the daggers of his assassins. He reduced the old republican institutions to empty forms, by making the magistrates mere creatures of his will. He issued the sternest edicts against the rebels, particularly by the law known as the "Polverina," from the name of its proposer Jacopo Polverini. This law decreed not only the confiscation of the property of exiles, but likewise that of their heirs, even if personally acquired by the latter. Cosimo ruled like the independent sovereign of a great state, and always showed the capacity, firmness, and courage demanded by that station. Only, his state being small and weak, he was forced to rely chiefly upon his personal talent and wealth. It was necessary for him to make heavy loans to the different European sovereigns, especially to Charles V., the most rapacious of them all, and to give enormous bribes to their ambassadors. Besides, he had to carry on wars for the extension of his dominions, and neither his inherited wealth nor the large sums gained by confiscating the estates of rebellious subjects sufficed for all this outlay. He was accordingly compelled to burden the people with taxes, and thus begin at once to diminish its strength.

Cosimo bore a special grudge against the neighbouring republics of Siena and Lucca. Although the latter was small and weak, and the former garrisoned by Spaniards, yet the spectacle of free institutions at the frontiers of his own state served as a continual incitement to subjects disaffected to the new régime. In fact Francesco Burlamacchi, a zealous Lucchese patriot, had conceived the design of re-establishing republican government in all the cities of Tuscany. Cosimo, with the emperor's help, succeeded in having him put to death. Lucca, however, was an insignificant state making no pretence of rivalry, whereas Siena was an old and formidable foe to Florence, and had always given protection to the Florentine exiles. It was now very reluctantly submitting to the presence of a Spanish garrison, and, being stimulated by promises of prompt and efficacious assistance from France, rose in rebellion and expelled the Spaniards in 1552. Cosimo instantly seized the opportunity, wrote to the emperor in terms that appealed to his pride, asked leave to attack Siena, and begged for troops to ensure the success of his enterprise. As no immediate answer arrived, he feigned to begin negotiations with Henry II. of France, and, by thus arousing the imperial jealousy, obtained a contingent of German and Spanish infantry. Then came a long and bloody war. Siena was besieged for fifteen months, and its inhabitants, aided by the valour of Piero Strozzi, who fought under the French flag, made a most heroic resistance, even women and children helping on the walls. But fortune was against them. Piero Strozzi sustained several defeats, and finally the Sienese, having exhausted their ammunition and being decimated by famine and the sword, were obliged to capitulate on honourable terms that were shamelessly violated. By the varied disasters of the siege and the number of fugitives the population was reduced from forty to eight thousand inhabitants. The republicans, still eager to resist, withdrew to Montalcino. Cosimo now ruled the city and territory of Siena in the name of Charles V., who always refused him its absolute possession. After the emperor's abdication, and the succession of Philip II. to the Spanish throne, Cosimo at last obtained Siena and Portoferra by giving up his claim to a sum of 200,000 ducats that he was to have received from Charles V. In 1559 he also captured Montalcino, and thus formed the grand-duchy of Tuscany, but he continued to govern the new state —*i.e.*, Siena and its territories—separately from the old. His rule was intelligent, skilful, and despotic; but his enormous expenses drove him to raise large sums of money by special contrivances unsuited to the country and the people. Hence, notwithstanding the genius of its founder, the grand-duchy held from the first the elements of its future decay. Cosimo preferred to confer office upon men of humble origin in order to have pliable tools, but he also liked to be surrounded by a courtier aristocracy on the Spanish and French pattern. As no Tuscan aristocracy any longer existed, he created new nobles, and tempted foreign ones to come by the concession of various feudal privileges; and, in order to turn this artificial aristocracy to some account, he founded the knightly order of St Stephen, charged with the defence of the coast against pirates, which in course of time won much honour by its prowess. He also established a small standing army for the protection of his frontiers; but, as we have seen, he generally employed German and Spanish troops for his wars, and always had a foreign bodyguard. At the commencement of his reign he opposed the popes in order to maintain the independence of his own state; but later, to obtain help, he truckled to them in many ways, even to the extent of giving up to the Inquisition his own confidant, Piero Carnesecchi, who, being accused of heresy, was beheaded and burnt in 1567. In reward for these acts of submission, the popes showed him friendship, and Pius V. granted him the title of grand-duke, conferring the patent and crown upon him in Rome, although the emperor had always withheld his consent. Finally, however, the latter confirmed the title to Cosimo's successor. The measure most injurious to Tuscany was the fiscal system of taxes, of which the sole aim was to extort the greatest possible amount of money. The consequent damage to industry, commerce, and agriculture was immense, and, added to the devastations caused by the Sienese war, led to their utter ruin. Otherwise Cosimo did not neglect useful measures for the interior prosperity of his state. He was no Mæcenas, but nevertheless restored the Pisan university, enlarged that of Siena, had the public records classified, and also executed public works like the Santa Trinità bridge. During the great inundations of 1557 he turned his whole energy to the relief of the sufferers.

Title of grand-duke.

In 1539 he had espoused Eleonora of Toledo, daughter of the viceroy of Naples, by whom he had several children. Two died in 1562, and their mother soon followed them to the grave. It was said that one of these boys, Don Garcia, had murdered the other, and then been killed by the enraged father. Indeed Cosimo was further accused of having put his own wife to death; but neither rumour had any foundation. He now showed signs of illness and failure

of strength. He was not old, but worn by the cares of state and self-indulgence. Accordingly in 1564 he resigned the government to his eldest son, who was to act as his lieutenant, since he wished to remain the virtual head of the state and have power to resume the sceptre on any emergency. In 1570, by the advice of Pius V., he married Camilla Martelli, a young lady of whom he had been long enamoured. In 1574 he died, at the age of fifty-four years and ten months, after a reign of thirty-seven years, leaving three sons and one daughter besides natural children. These sons were Francesco, his successor, who was already at the head of the government, Cardinal Ferdinand, and Piero.

Francesco I. Francesco I., born in 1541, began to govern as his father's lieutenant in 1564, and was married in 1565 to the archduchess Giovanna of Austria. On beginning to reign on his own account in 1574, he speedily manifested his real character. His training in the hands of a Spanish mother had made him suspicious, false, and despotic. Holding everyone aloof, he carried on the government with the assistance of a few devoted ministers. He compelled his stepmother to retire to a convent, and kept his brothers at a distance from Florence. He loved the privileges of power without its burdens. Cosimo had known how to maintain his independence, but Francesco cast himself like a vassal at Austria's feet. He reaped his reward by obtaining from Maximilian II. the title of grand-duke, for which Cosimo had never been able to win the imperial sanction, but he forfeited all independence. Towards Philip II. he showed even greater submissiveness, supplying him with large sums of money wrung from his over-taxed people. He held entirely aloof from France, in order not to awake the suspicions of his protectors. In short, under his rule the history of Tuscany was reduced to a mere record of local and municipal events. To increase his funds, he traded on his own account, thus creating a monopoly that was ruinous to the country at large, and led to an enormous number of failures. He raised the tax upon corn to so high a rate that few continued to find any profit in growing it, and thus the Maremme, already partly devastated during the war with Siena, were converted into a desert. Even industry declined under this system of government; and, although Francesco founded porcelain manufactories and pietra dura works, they did not rise to any prosperity until after his death. His love of science and letters was the only Medicean virtue that he possessed. He had an absolute passion for chemistry, and passed much of his time in his laboratory. Sometimes indeed he gave audience to his secretaries of state standing before a furnace, bellows in hand. He took some useful measures to promote the rise of a new city at Leghorn, which at that time had only a natural and ill-sheltered harbour. The improvement of Leghorn had been first projected by Cosimo I., and was carried on by all the succeeding Medici. Francesco was a slave to his passions, and was led by them to scandalous excesses and deeds of bloodshed. His example and neglect of the affairs of the state soon caused a vast increase of crime even among the people, and, during the first eighteen months of his reign, there occurred no less than one hundred and sixty-eight murders.

In default of public events, the historians of this period enlarge upon private incidents, generally of a scandalous or sanguinary kind. In 1575 Orazio Pucci, wishing to avenge his father, whom Cosimo had hanged, determined to get up a conspiracy, but, soon recognizing how firmly the Medicean rule had taken root in the country, desisted from the attempt. But the grand-duke, on hearing of the already abandoned plot, immediately caused Pucci to be hanged from the same window of the Palazzo Vecchio, and even from the same iron stanchion, from which his father before him had hung. His companions, who had fled to France and England, were pursued and murdered by the ducal emissaries. Their possessions were confiscated, and the "Polverina" law applied so that the conspirators' heirs were reduced to penury, and the grand-duke gained more than 300,000 ducats.

Next year Isabella dei Medici, Francesco's sister, was strangled in her nuptial bed by her husband, Paolo Giordano Orsini, whom she had betrayed. Piero dei Medici, Francesco's brother, murdered his wife Eleonora of Toledo from the same motive. Still louder scandal was caused by the duke's own conduct. He was already a married man, when, passing one day through the Piazza of St Mark in Florence, he saw an exceedingly beautiful woman at the window of a mean dwelling, and at once conceived a passion for her. She was the famous Bianca Cappello, a Venetian of noble birth, who had eloped with a young Florentine named Pietro Buonaventuri, to whom she was married at the time that she attracted the duke's gaze. He made her acquaintance, and, in order to see her frequently, nominated her husband to a post at court. Upon this, Buonaventuri behaved with so much insolence, even to the nobility, that one evening he was found murdered in the street. Thus the grand-duke, who was thought to have sanctioned the crime, was able to indulge his passion unchecked. On the death of the grand-duchess in 1578 he was privately united to Bianca, and afterwards married her publicly. But she had no children, and this served to poison her happiness, since the next in succession was her bitter enemy, the cardinal Ferdinand. The latter came to Florence in 1587, and was ostentatiously welcomed by Bianca, who was most anxious to conciliate him. On October 18th of the same year, the grand-duke died at his villa of Poggio a Caiano, of a fever caught on a shooting excursion in the Maremme, and the next day Bianca also expired, having ruined her health by drugs taken to cure her sterility. But rumour asserted that she had prepared a poisoned tart for the cardinal, and that, when he suspiciously insisted on the grand-duke tasting it first, Bianca desperately swallowed a slice and followed her husband to the tomb.

Such was the life of Francesco dei Medici, and all that can be said in his praise is that he gave liberal encouragement to a few artists, including Giovanni Bologna, who executed for him the group of the Rape of the Sabines. He was the founder of the Uffizi gallery, of the Medici theatre, and the villa of Pratolino; and during his reign the Della Crusca academy was instituted.

Ferdinand I. Ferdinand I. was thirty-eight years of age when, in 1587, he succeeded his brother on the throne. A cardinal from the age of fourteen, he had never taken holy orders. He showed much tact and experience in the management of ecclesiastical affairs. He was the founder of the Villa Medici at Rome, and the purchaser of many priceless works of art, such as the Niobe group and many other statues afterwards transported by him to Florence. After his accession he retained the cardinal's purple until the time of his marriage. He was in all respects his brother's opposite. Affable in his manners and generous with his purse, he chose a crest typical of the proposed mildness of his rule,—a swarm of bees with the motto *Majestate tantum*. He instantly pardoned all who had opposed him, and left his kinsmen at liberty to choose their own place of residence. Occasionally, for political reasons, he committed acts unworthy of his character; but he re-established the administration of justice, and sedulously attended to the business of the state and the welfare of his subjects. Accordingly Tuscany revived under his rule and regained the independence and political dignity that his brother had sacrificed to love of ease and personal indulgence. He favoured commerce, and effectually ensured the prosperity of Leghorn, by an edict enjoining toleration towards Jews and

heretics, which led to the settlement of many foreigners in that city. He also improved the harbour and facilitated communication with Pisa by means of the Naviglio, a canal into which a portion of the water of the Arno was turned. He nevertheless retained the reprehensible custom of trading on his own account, keeping banks in many cities of Europe. He successfully accomplished the draining of the Val di Chiana, cultivated the plains of Pisa, Fucecchio, and Val di Nievole, and executed other works of public utility at Siena and Pisa. But his best energies were devoted to the foreign policy by which he sought to emancipate himself from subjection to Spain. On the assassination (1589) of Henry III. of France, Ferdinand supported the claims of the king of Navarre, undeterred by the opposition of Spain and the Catholic League, who were dismayed by the prospect of a Huguenot succeeding to the throne of France. He lent money to Henry IV., and strongly urged his conversion to Catholicism; he helped to persuade the pope to accept Henry's abjuration, and pursued this policy with marvellous persistence until his efforts were crowned with success. Subsequently, however, Henry IV. showed faint gratitude for the benefits conferred upon him, and paid no attention to the expostulations of the grand duke, who then began to slacken his relations with France, and showed that he could guard his independence by other alliances. He gave liberal assistance to Philip III. for the campaign of the latter in Algiers, and to the emperor for the war with the Turks. Hence he was compelled to burden his subjects with enormous taxes, forgetting that while guaranteeing the independence of Tuscany by his loans to foreign powers he was increasingly sapping the strength of future generations. He at last succeeded in obtaining the formal investiture of Siena, which Spain had always considered a fief of her own.

During this grand-duke's reign the Tuscan navy was notably increased, and did itself much honour on the Mediterranean. The war-galleys of the knights of St Stephen were despatched to the coast of Barbary to attack Bona, the headquarters of the corsairs, and they captured the town with much dash and bravery. And in the following year (1608) the same galleys achieved their most brilliant victory in the archipelago over the stronger fleet of the Turks, by taking nine of their vessels, seven hundred prisoners, and a store of jewels of the value of 2,000,000 ducats.

Cosimo II.

Ferdinand I. died in 1609, leaving four sons, of whom the eldest, Cosimo II., succeeded to the throne at the age of nineteen. He was at first assisted in the government by his mother and a council of regency. He had a good disposition, and the fortune to reign during a period when Europe was at peace and Tuscany blessed with abundant harvests. Of his rule there is little to relate. His chief care was given to the galleys of St Stephen, and he sent them to assist the Druses against the Porte. On one occasion he was involved in a quarrel with France. Concino Concini, the Marshal d'Ancre, being assassinated in 1617, Louis XIII. claimed the right of transferring the property of the murdered man to De Luynes. Cosimo opposed the decision, and, refusing to recognize the confiscation decreed by the French tribunals, demanded that Concini's son should be allowed to inherit. Hence followed much ill-feeling and mutual reprisals between the two countries, finally brought to an end by the intervention of the duke of Lorraine.

Like his predecessors, Cosimo II. studied to promote the prosperity of Leghorn, and he deserves honour for abandoning all commerce on his own account. But it was no praiseworthy act to pass a law depriving women of almost all rights of inheritance. By this means many daughters of the nobility were driven into convents against their will. He gave scanty attention to the general affairs of the state. He was fond of luxury, spent freely on public festivities, and detested trouble. Tuscany was apparently tranquil and prosperous; but the decay of which the seeds were sown under Cosimo I. and Ferdinand I. was rapidly spreading, and became before long patent to all and beyond all hope of remedy. The best deed done by Cosimo II. was the protection accorded by him to Galileo Galilei, who had removed to Padua, and there made some of his grandest discoveries. The grand-duke recalled him to Florence in 1610, and nominated him court mathematician and philosopher. Cosimo died in February 1621, after twelve years of a quiet reign marked by no great event. Feeling his end draw near, when he was only aged thirty and all his sons were still in their childhood, he hastened to arrange his family affairs. His mother, Cristina of Lorraine, and his wife, Maddalena of Austria, were nominated regents and guardians to his eldest son Ferdinand II., a boy of ten, and a council of four appointed, whose functions were regulated by law. Accordingly, after Cosimo's death, the young Ferdinand was sent to Rome and Vienna to complete his education, and the government of Tuscany remained in the hands of two jealous and quarrelsome women. Thus the administration of justice and finance speedily went to ruin. Out of submissiveness to the pope, the regents did not dare to maintain their legitimate right to inherit the duchy of Urbino, and in 1623 sanctioned the transfer of that right to the holy see. They conferred exaggerated privileges on the new Tuscan nobility, which became increasingly insolent and worthless. They resumed the practice of trading on their own account, and, without reaping much benefit thereby, did the utmost damage to private enterprise.

Ferdinand II.

In 1627 Ferdinand II., then aged seventeen, returned to Italy and assumed the reins of government; but, being of a very gentle disposition, he decided on sharing his power with the regents and his brothers, and arranged matters in such wise that each was almost independent of the other. He gained the love of his subjects by his great goodness; and, when Florence and Tuscany were cruelly ravaged by the plague in 1630, he showed admirable courage, and carried out many useful measures. But he was totally incapable of energy as a statesman. When the pope made bitter complaints because the board of health had dared to subject certain monks and priests to the necessary quarantine, the grand-duke insisted on his officers asking pardon on their knees for having done their duty. On the death in 1631 of the last duke of Urbino, the pope was allowed to seize the duchy without the slightest opposition on the part of Tuscany. As a natural consequence the pretensions of the Roman curia became increasingly exorbitant; ecclesiastics usurped the functions of the state; and the ancient laws of the republic, together with the regulations decreed by Cosimo I. as a check upon similar abuses, were allowed to become obsolete. On the extinction of the line of the Gonzagas at Mantua in 1627, war broke out between France on the one side and Spain, Germany, and Savoy on the other. The grand-duke, uncertain of his policy, trimmed his sails according to events. Fortunately peace was re-established in 1631. Mantua and Monferrato fell to the duke of Nevers, as France had always desired. But Europe was again in arms for the Thirty Years' War, and Italy was not at peace. Urban VIII. wished to aggrandize his nephews, the Barberini, by wresting Castro and Ronciglione from Odoardo Farnese, duke of Parma and brother-in-law to Ferdinand. Farnese determined to maintain his rights, and marched his army through Tuscany into the territories of the pope, who was greatly alarmed by the attack. Naturally the grand-duke was drawn into the war to defend his own state and his kinsman. His military operations, however, were of the feeblest and often the most laughable character. At

last, by means of the French intervention, peace was made in 1644. But, although the pope was forced to yield, he resigned none of his ecclesiastical pretensions in Tuscany. It was during Ferdinand's reign that the septuagenarian Galileo was obliged to appear before the Inquisition in Rome, which treated him with infamous cruelty. On the death of this great and unfortunate man, the grand-duke wished to erect a monument to him, but was withheld by fear of the opposition of the clergy. The dynasty as well as the country now seemed on the brink of decay. Two of the grand-duke's brothers had already died childless, and Ippolito, the sole survivor, was a cardinal. Accordingly the only remaining heir was Cosimo III., married to a wife who held him in detestation, and did her best to have her marriage annulled or at least obtain a separation.

Like nearly all his predecessors, Ferdinand II. gave liberal patronage to science and letters, greatly aided therein by his brother Leopold, who had been trained by Galileo Galilei, and who joined with men of learning in founding the celebrated academy *Del Cimento*, of which he was named president. This academy took for its motto the words *Provando e riprovando*, and followed the experimental method of Galileo. Formed in 1657, it was dissolved in 1667 in consequence of the jealousies and dissensions of its members, but during its brief existence won renown by the number and importance of its works.

Cosimo III.

Cosimo III. succeeded his father in 1670. He was weak, vain, bigoted, and hypocritical. In 1661 he had espoused Louise d'Orléans, niece of Louis XIV., who, being enamoured of Duke Charles of Lorraine, was very reluctant to come to Italy, and speedily detested both her husband and his country, of which she refused to learn the language. She had two sons and one daughter, but after the birth of her third child, Giovan Gastone, her hatred for her husband increased almost to madness. She first withdrew to Poggio a Caiano, and then, being unable to get her marriage annulled, returned to France, where, although supposed to live in conventual seclusion, she passed the greater part of her time as a welcome visitor at court. Even her testamentary dispositions attested the violence of her dislike to her husband.

Cosimo's hypocritical zeal for religion compelled his subjects to multiply services and processions, that greatly infringed upon their working hours. He wasted enormous sums in pensioning converts—even those from other countries—and in giving rich endowments to sanctuaries. Meanwhile funds often failed for the payment of Government clerks and soldiers. His court was composed of bigots and parasites; he ransacked the world for dainties for his table, adorned his palace with costly foreign hangings, had foreign servants, and filled his gardens with exotic plants. He purchased from the emperor the title of "Highness" in order to be the equal of the duke of Savoy. He remained neutral during the Franco-Spanish war, and submitted to every humiliation and requisition exacted by the emperor. He had vague notions of promoting agriculture, but accomplished no results. At one time he caused eight hundred families to be brought over from the Morea for the cultivation of the Maremme, where all of them died of fever. But when, after the revocation of the edict of Nantes, French Huguenots offered to apply their labour and capital to the same purpose, the grand-duke's religious scruples refused them refuge. So ruin fell upon Tuscany. Crime and misery increased, and the poor, who only asked for work, were given alms and sent oftener to church. This period witnessed the rise of many charitable institutions of a religious character under the patronage of the grand duke, as for instance the congregation of San Giovanni Battista. But these could not remedy the general decay.

Cosimo's dominant anxiety regarded the succession to the throne. His eldest son Ferdinand died childless in 1713. The pleasure-loving Giovan Gastone was married to Anna Maria of Saxe-Lauenburg, widow of a German prince, a wealthy coarse woman wholly immersed in domestic occupations, and who seemed little likely to give birth to any children. After living with her for some time in a Bohemian village, Giovan Gastone yielded to his dislike to his wife and her country, withdrew to France, and ruined his health by his excesses. After a brief return to Bohemia he finally separated from his wife, by whom he had no family. Thus the dynasty was doomed to extinction. Cosimo had a passing idea of reconstituting the Florentine republic, but, this design being discountenanced by the European powers, he determined to transfer the succession, after the death of Giovan Gastone, to his sister Anna Maria Louisa, who in fact survived him. For this purpose he proposed to annul the patent of Charles V., but the powers objected to this arrangement also, and by the treaty of 1718 the quadruple alliance of Germany, France, England, and Holland decided that Parma and Tuscany should descend to the Spanish Infante Don Carlos. The grand-duke made energetic but fruitless protests.

Cosimo III. had passed his eightieth year at the time of his decease in October 1723, and was succeeded by his son Giovan Gastone, then aged fifty-three. The new sovereign was in bad health, worn out by dissipation, and had neither ambition nor aptitude for rule. His throne was already at the disposal of foreign powers, and his only thought on ascending it was to regain strength enough to pass the remainder of his days in enjoyment. He dismissed the spies, parasites, and bigots that had formed his father's court, abolished the pensions given to converts, suppressed several taxes, and prohibited the organized espionage established in the family circle. He wished to live and let live, and liked the people to be amused. Everything in fact bore a freer and gayer aspect under his reign, and the Tuscans seemed to feel renewed attachment for the dynasty as the moment of its extinction drew near. But the grand-duke was too feeble and incapable to accomplish any real improvement. Surrounded by gay and dissipated young men, he entrusted all the cares of government to a certain Giuliano Dami, who drove a profitable trade by the sale of offices and privileges. In this way all things were in the hands of corrupt individuals; while the grand-duke, compelled to pass the greater part of his time in bed, vainly sought diversion in the company of buffoons, and was only tormented by perceiving that all the world disposed of his throne without even asking his advice. And when, after prolonged opposition, he had resigned himself to accept Don Carlos as his successor, the latter led a Spanish army to the conquest of Naples, an event afterwards leading to the peace of 1735, by which the Tuscan succession was transferred to Francesco II., duke of Lorraine, and husband of Maria Theresa. Giovan Gastone was finally obliged to submit even to this. Spain withdrew her garrisons from Tuscany, and Austrian soldiers took their place and swore fealty to the grand-duke on the 5th of February 1737. He expired on the 9th July of the same year. Such was the end of the younger branch of the Medici, which had found Tuscany a prosperous country, where art, letters, commerce, industry, and agriculture flourished, and left her poor and decayed in all ways, drained by taxation, and oppressed by laws contrary to every principle of sound economy, downtrodden by the clergy, and burdened by a weak and vicious aristocracy.

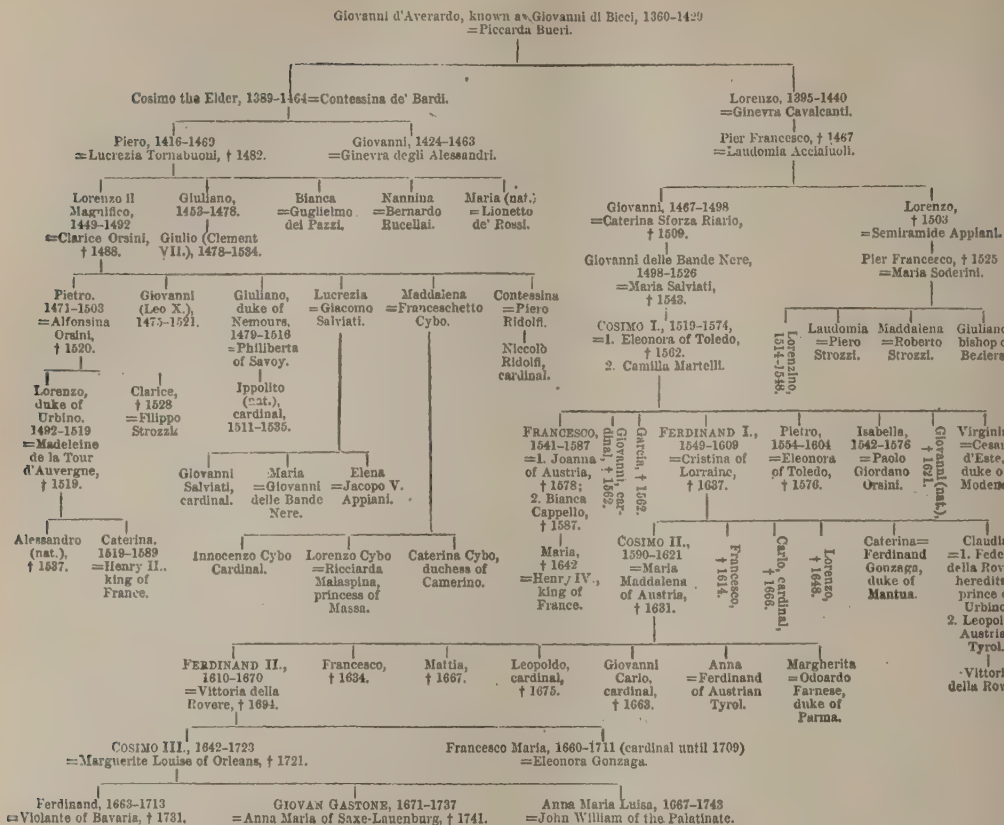
GENEALOGICAL TABLE OF THE MEDICI.



# MEDICINE

## PART I.—SYNOPTICAL VIEW OF MEDICINE.

MEDICINE, the subject-matter of one of the learned professions, includes, as it now stands, a wide range of scientific knowledge and practical skill. The history of its growth from small beginnings in Greece is traced in the second section of the present article; it remains here to give a synoptical view of medicine, including its scientific or philosophical position, its subdivisions or ramifications as an art and discipline, and its relations to the body politic.

*Scientific Position of Medicine.*—The science of medicine is the theory of diseases and of remedies. While the notion of disease is necessarily or inevitably correlated with the notion of health, there is no necessary and invariable relation, but, on the other hand, a merely conventional association, between a disease and a remedy. That part of the science of medicine which corresponds to the theory of remedies is not therefore in a position scientifically inferior to the theory of diseases; for each article of the materia medica—apart from a few inert substances—has a certain effect on the organism in health and in disease, which is ascertainable with scientific precision. Those properties and actions of drugs are the subject of pharmacology and toxicology; the circumstances under which the several articles of the materia medica become remedial are the subject of therapeutics, and therapeutics is dependent for its scientific position upon the completeness of the theory of diseases, or pathology.

Disease is the correlative of health, and the word is not capable of a more penetrating definition. From the time of Galen, however, it has been usual to speak of the life of the body either as proceeding in accordance with nature (*κατὰ φύσιν, secundum naturam*) or as overstepping the bounds of nature (*παρὰ φύσιν, præter naturam*). Taking disease to be a deflexion from the line of health, the first requisite of medicine is an extensive and intimate acquaintance with the norm of the body. The normal condition of the body is capable of being determined without ambiguity; it is the absence from its structures and functions of every disease hitherto known. The structure and functions of the body form the subject of anatomy and physiology.

Physiology is, strictly speaking, the science of that which is *κατὰ φύσιν*, or *secundum naturam*, and it is usual to say that the theory of diseases is based upon physiology. But, although all that was implied in the Hippocratic term *φύσις* (*natura*) may be claimed as the subject-matter of physiology, yet, in the ordinary connotation of the term, physiology divides the empire with anatomy. To physiology the functions of the body are usually assigned, and to

anatomy its form and structure. But, as a matter of fact, the structures and functions of the organism are not separable; structure is correlated to function, whether active, dormant, or extinguished, and in like manner function is the twin notion of structure. In the ultimate analysis neither term means anything without the other, and both together mean life. It is owing mostly to its name that physiology is supposed to have a preponderant interest for the theory of disease; the word anatomy is not well adapted to carry its own half of the structure-and-function dualism. Both in the historical development and in the logical connotation, anatomy is as much associated with the living and moving body as physiology itself; but its etymology has always been against it, and it has become more and more difficult to retain for anatomy anything beyond the technicalities of the dissecting-room. The subject of general anatomy has for the most part disappeared from modern text-books, its place being taken by histology, which deals with the minute structure of the simple tissues, and, in a wider acceptation, with the finer anatomy of all the organs and parts of the body. Histology, like anatomy, has had a somewhat technical or descriptive rôle assigned to it; and it is now mainly under physiology that the processes, activities, or living mechanisms of the body fall to be considered. The development of the body as a whole, and of its several tissues and organs, forms the subject of embryology; many of the physiological types of diseased processes, especially the cellular, are discoverable in the embryological period. For the period of development, no arbitrary separation has been attempted hitherto between structure and function, and embryology is, in theory at least, as much physiological as anatomical. The development of function is a legitimate and even desirable subject of scientific study, and a more distinctive place is probably awaiting it in the future: but so indissoluble does the union of structure and function present itself in the period of genesis and growth that the function has hardly as yet come to be abstracted from the structure, or the structure from the function.

The theory of disease rests, therefore, upon physiology, with its more or less technical adjuncts. Pathology is all that physiology is, with the engrossing and difficult element of perturbation, deflexion, or shortcoming added. By virtue of this element of deviation from the line of health, pathology is a discipline apart, with an abundant literature of its own, and with separate academical institutes and chairs. But pathology is also a discipline apart by virtue of concepts proper to itself. A great part of the theory of disease deals with changes or defects of structure and perturbations or failings of function, which may be intricate or difficult to analyse, but are still well within sight of the line of health. Such are the common diseases of the organs and systems—the inflammations, catarrhs, degenerations, hypertrophies, and functional derangements without lesion of the respiratory, circulatory, nervous, genito-urinary, locomotor, and cutaneous systems. Constitutional or general diseases belong also to the province of perturbations from the physiological course,—such diseases as chlorosis, leukæmia, diabetes, gout, rheumatism, scurvy, rickets, Addison's disease, exophthalmic goitre, and the febrile state. Again, congenital deficiencies or malformations, non-cancerous tumours, and the repairing of injuries exemplify no other laws than those of development and growth.

But with those examples the catalogue of physiological diseases is exhausted. We are left with a vast residue of diseases, which have always bulked largely in the popular mind, and have carried the most terrible associations with them. Such are the pestilences or diseases of peoples:—the plague, sweating sickness, cholera, yellow fever, typhus fever, relapsing fever, typhoid fever, diphtheria, small-pox, measles, scarlet fever, influenza, dengue. Such also are the cancers, consumptions, leprosies, and other loathsome infections. This enormous residue is more than the half of disease, and the definition of disease or the scheme of pathology is brought to a test in finding room within its scientific categories for such maladies as those. The popular imagination in all countries has personified them; medicine in its metaphysical period has regarded them as entities or things in themselves; and it remains to be seen in what way or to what extent medicine in its scientific period will bring them within the category of perturbations of the physiological life.

In considering, for a moment, where to place cancer in the pathological scheme, we shall arrive at a point of view from which the relation of the acute and chronic infections (or contagions) to diseases of the physiological order may be contemplated at least provisionally. Taking cancers, in a generic sense, to mean tumours that have acquired or are possessed of malignancy, we find that such tumours have many points in common with simple tumours,—that they have grown out of the tissues of particular organs or parts under particular (functional) circumstances, and that they may, in general terms, be traced back to that point at which they left the line of health (see PATHOLOGY). The tracing back of tumours along the physiological track is often difficult and laborious; but there is no tumour of the body whose origins are not at length discoverable within the limits of physiological action. That which makes any tumour a cancer is something over and beyond; it is a remarkable acquired property of reproducing its structure in manifold copies, or of infecting the organism of which it is itself a part. The tumour thus becomes a semi-independent power within the body; it may be said, in a political figure, to have acquired *autonomy*, or to have become *imperium in imperio*. A due consideration of such a phenomenon as the infectiveness or cancerousness of some tumours will satisfy one that there are concepts in pathology which carry the investigator entirely beyond physiological bounds or out of sight of the line of health, which bring him face to face with the notion of a disease as a thing in itself, and which thus constitute a peculiar subject-matter. There is nothing that we know among biological phenomena altogether analogous to the semi-independence which an integral part of the body, or condition of the body, manifests towards the organism as a whole, and that, too, strictly in respect of its acquired devious or rebellious habit. The familiar definition of disease, *morbus est vita præter naturam*, which embodies the notion of divergence from the line of health, makes no provision for an acquired autonomy of a morbid state; and that definition has to be supplemented by another, which will recognize the possibility of a disease becoming a thing in itself. The old definition of Van Helmont, *morbus est ens reale subsistens in corpore*, appears to satisfy the requirement; but that definition, although it grew out of the phenomena of disease as observed in fevers, was made too general, and has now associations that are too exclusively ontological and metaphysical. The supplementary definition should be as far as possible in the terms of the principal definition; and we shall provide best in the pathological scheme for such a disease as cancer if, in addition to the formula *morbus est vita præter naturam*, we construct a secondary formula, *morbus est vivum in vivo*.

The notion of autonomy acquired by a morbid state implies, naturally, a pre-autonomous stage of the disease, which had been a mere perturbation of the norm of the body, capable of being measured by the physiological standard. The autonomous stage and the pre-autonomous

stage, which may be demonstrated, in individual cases, for cancers, are a philosophical necessity for all other infective diseases that are marked by morphological features, or by structural characters rooted in and growing out of the proper textures of the body. Thus the peculiar skin eruption of small-pox, which is communicable from person to person, along with a distinctive course of fever, must have had pre-autonomous antecedents (not altogether historically vague) in certain casual conditions of the skin and associated constitutional disturbance, which had recurred and become inveterate, and had so attained to a degree of individuality or a point of autonomy at which they began to be propagated as an organic unit Again, a second group of infections, exemplified by glanders, bovine tubercle, and syphilis, are rooted in deeper textural processes, which must have been at one time (and may still be) set up by the casual operation of ordinary causes, and at length became the occasion of infective mimicry. It is not so easy to picture (and it is not difficult, with a modern dominant school, to ignore) the casual morbid conditions or ordinary physiological perturbations out of which powerful infections like cholera, typhoid fever, or yellow fever may have arisen; but if the rise and consolidation of their autonomy be a subtle or even untraceable history, yet there are diseases, such as dysentery and erysipelas, which are apt to occur both as casual or spontaneous conditions and as specific infections side by side. Ophthalmia is an example of a purulent catarrh which is constantly arising *de novo* in Egypt from local causes in a non-infective manner, and yet has become, on at least one memorable occasion, a powerful and widespread infection for British troops returning from that country and for the home garrisons for many years subsequently. Infective pneumonia in cattle, and more rarely in man, is an analogous case. In such an episode we observe the actual rise of the disease-autonomy. Again, all the infective diseases have degrees of intensity, at one extreme of which there must occur the vanishing point of their infective property; and those gradations of infectiveness are nowhere more noticeable than in the relation of cholera to choleraic diarrhœa. Further, the remarkable group of climatic fevers are not communicable from person to person (see MALARIA); in that respect, and for the reason that the liability of the patient is anything but exhausted by one attack, they are examples of fevers without autonomy. There is not one of the infections that may not be profitably studied from the point of view of its autonomy, and of its more or less obscure pre-autonomous stage. That is a point of view from which even the pestilences and other specific diseases may be regarded as coming within the physiological categories. The large residue of diseases, which are more than perturbations of the physiological life, may still be joined by natural descent to the class of simple perturbations, if we can show for them how their autonomy was acquired, or what was their origin as disease-species.

There is an established place in the history of medicine, and there ought therefore to be room in the definition of disease, for epidemic outbreaks of purely psychical diseased states, such as the dancing madness (*Tanzwuth*), and the boys' crusades; the epidemic diffusion of such morbid states is best approached from the point of view of an acquired autonomy (fixed idea) and an infective mimicry.

The physiological definition of disease, *morbus est vita præter naturam*, affords no place for parasitic diseases. However, the supplementary formula that has been proposed to meet the case of diseases existing autonomously in the body, *morbus est vivum in vivo* will meet the case of parasitic diseases also. According to many pathologists of the present generation, the whole class of pestilences, fevers, and specific infections generally are caused by certain species of minute parasites invading the body; according to one form of that hypothesis the distinctive characters or specific marks (morphological and other) of those diseases are neither more nor less than the appropriate effects wrought upon the textures and fluids of the body by the respective species of parasites. In this way the great group of infective diseases, which are apt to be the stumbling-block of a scientific definition and logical scheme of disease, are easily disposed of by placing them beside the otherwise insignificant group of parasitic diseases. Whether all or any of those diseases are due in a sense to the invasion of parasites, or wholly caused by parasites, are questions that naturally fall to be settled by a careful sifting of a mass of evidence which has already proved to be peculiarly rich in opportunities for mistake. It may be expected that the facts of infective parasitism and the facts of acquired disease-autonomy will in the end find their place in a common theory of specific diseases, which might be expressed in terms of the physiological formula *morbus est vita præter naturam* with the rider *morbus est vivum in vivo*

The theory of remedies, which forms the second division of the science of medicine, is chiefly based upon pharmacology or toxicology. If pharmacology be considered as not co-extensive with toxicology, it will be taken to be in great part pharmacographia, or the systematic description of articles of the materia medica—their source, preparation, physical properties, and the like. Toxicology is in its general sense the investigation of the physiological action of drugs, a science which is largely dependent upon experiments on the lower animals; in a more technical sense toxicology relates to the effects of poisons and the art of detecting them (see POISONS). The physiological action of drugs is the key to their therapeutical action. Therapeutics has been defined as "the discovery of the means by which a system of forces competent to eliminate any given perturbation may be introduced into the economy." The adaptation of remedies to diseases is, however, greatly wanting in precision, and continues to be in large part empirical and traditional. It may be objected to the above definition that all diseases are not reducible to the category of "perturbations," and that there is a certain scientific justification for the doctrine of specifics. Besides the articles of the materia medica proper, agencies such as electricity, baths, sea-voyages, and changes of climate generally, enter into the consideration of therapeutics, and two of those form the subject of special departments, viz., electro-therapeutics and hydropathy. Regimen and diet are also important factors in the treatment of disease; according to a contention of Hippocrates, it was in the dietetic needs of mankind that the medical art had its origin.

*Subdivisions of Medicine as an Art and Discipline.*—The medical art (*ars medendi*) breaks away at once from the unity of the theory of disease. While there is but one body of pathological doctrine for either sex, for every period of life, and for every region and part of the organism, the practical art divides itself into departments and subdepartments. The most fundamental division is into internal and external medicine, or into medicine proper and surgery. The treatment of wounds, injuries, and deformities, with operative interference in general, is the special department of surgical practice (the corresponding parts of pathology, including inflammation, repair, and removable tumours, are sometimes grouped together as surgical pathology); and where the work of the profession is highly subdivided, surgery becomes the exclusive province of the surgeon, while internal medicine remains to the physician. A third great department of practice is

formed by obstetric medicine or midwifery, and with obstetrics there is usually associated gynæcology, or the diseases peculiar to women. Diseases of children are the subject of a voluminous separate literature. Dermatology (diseases of the skin) is an important province of practice which, like the diseases of women and children, pertains as much to medicine as to surgery. The greatest of the so-called special departments of practice is ophthalmology (diseases and injuries of the eye). Laryngology is a department that owes its existence mainly to the invention of the laryngoscope, its special province being the treatment of the inflammations (ordinary and specific), tumours, and the like, to which the larynx is liable in common with other parts. Diseases of the ear (otology) form even a more restricted department of practice, owing to the comparative inaccessibility of the chief part of the organ of hearing. The congenital condition of deaf-mutism may or may not be taken as falling within the province of the last-mentioned subdivision. Dentistry or odontology is extremely limited in the range of its subject-matter; but it affords great opportunities for refinements of technical skill, and it is given up to a distinct branch of the profession.

The care of the weak-minded and the insane (psychological medicine) is an integral part of medical practice, inasmuch as it is concerned with diseases of the nervous system and with numerous correlated states of other organs; but it occupies a unique place by reason of the engrossing interest of the subjective phenomena. Habitual drunkenness is also a subject of special treatment.

A state of war, actual or contingent, gives occasion to special developments of medical and surgical practice (military hygiene and military surgery). Wounds caused by projectiles, sabres, &c., are the special subject of naval and military surgery; while under the head of military hygiene we may include the general subject of ambulances, the sanitary arrangements of camps, and the various forms of epidemic camp sickness.

The administration of the civil and criminal law involves frequent relations with medicine, and the professional subjects most likely to arise in that connexion, together with a summary of *causes célèbres*, are formed into the department of medical jurisprudence. It is the practice in Great Britain to call independent medical evidence on both sides of a cause, whether the proceedings be civil or criminal.

The system of life assurance is based upon the co-operation of the medical profession. Heredity, constitution, and diathesis are here the chief subjects of general consideration, while prognosis is the skilled faculty specially called into play.

*Relations of Medicine to the Body Politic.*—The statutes of the United Kingdom which have direct relation to medicine are (1) those relating to the public health; (2) those relating to lunacy (and habitual drunkenness); (3) those relating to the status of the medical profession, to dentists, and to pharmaceutical chemists; (4) those relating to restrictions on the "practice" of anatomy and physiology. There are, besides, several statutes in which medicine is concerned indirectly,—such as the Poor Laws, the Prisons Acts, the Shipping Acts, the Registration of Births and Deaths Act, the Sale of Food and Drugs Act, the Sale of Poisons Act, the Factory and Workshops Act, the Artisans' Dwellings (Metropolitan) Act, the Rivers Pollution Prevention Act, the Contagious Diseases (Animals) Act (1878), and the Public Health (Water) Act.

1. Most of the statutes relating to the public health in England and Wales were consolidated by an Act of 1875, the Acts relating to the metropolis being excepted; there are separate statutes of about the same period for Ireland and Scotland. The system of administration is by local sanitary authorities, in correspondence with the local government boards in London and Dublin and the board of supervision in Edinburgh. The board in London has a medical department, consisting of a chief medical officer, assistant medical officer, and inspectors, while the Dublin and Edinburgh boards are professionally advised on a somewhat different system. The sanitary authorities throughout the United Kingdom are divided into rural, urban, port, and metropolitan (sanitary and nuisance); they are formed out of pre-existing bodies, either the corporations of cities and towns, the improvement commissioners, or the local authorities. A medical officer of health is attached to most of the several sanitary authorities, or to the combined sanitary authorities of a large district; his duties include making reports on the death-rate and the causes of mortality, the denunciation of nuisances and unwholesome dwellings, workshops, &c., inquiries into the local causes or favouring circumstances of epidemic outbreaks of disease, measures to prevent the spread of contagion (by disinfection, isolation, and otherwise), and other more occasional duties arising under a variety of statutes. Each sanitary authority is required by law to appoint an inspector of nuisances, who practically carries out the instructions of the medical officer when there is one.

The Vaccination Acts (consolidated 1871) are an important part of the public health law of the kingdom; they are administered by the local government board, for the most part through the agency of the medical profession at large, but in some populous parishes also by means of public vaccination stations. Prosecutions under the Acts are instituted by the parochial authorities. The practice formerly (and not unsuccessfully) resorted to of inoculating with the small-pox has been made a criminal offence; but there is still much uncertainty as to the theory of vaccination, and, in particular, as to the relation of vaccinia to variola.

Other statutes which were not consolidated in the Public Health Act of 1875 are the Burials Act, the Contagious Diseases Act, and the Quarantine Act. The first of these is administered by a department of the home office, with a medical inspector. The second (1866 and 1869) relates, under a too general title, to the regulation of prostitution in certain garrison towns, the surgeons under the act being appointed by the board of admiralty or the secretary of state for war, and the administration otherwise carried out by the police.

The quarantine laws stand in the somewhat anomalous position of statutes which it is not thought desirable to repeal, while yet they are stripped bare of all their executive machinery. The Quarantine Act can be set in motion, as occasion arises, by an order of council; not only, however, is there no official medical advice at the disposal of the privy council, upon which action under the act might be taken, but there is not even the framework remaining (except the ghost of a quarantine station on the Motherbank between Portsmouth and the Isle of Wight) of the once considerable quarantine establishment, by which the provisions of the Act might be enforced. On the other hand, port sanitary authorities enjoy certain limited powers under the Public Health Acts of isolating vessels arriving with contagious sickness on board. A quarantine at British ports has not been put in force for many years, opinions being divided as to the abstract efficacy and suitableness of quarantine measures to prevent the importation and diffusion of plague, cholera, or yellow fever (see QUARANTINE).

Numerous instances having occurred of the extensive diffusion of scarlet fever, typhoid fever, and diphtheria by means of milk, the privy council has issued an order, under the Contagious Diseases (Animals) Act of 1878, called the Dairies, Milkshops, and Cowsheds Order, with the object of enforcing extreme cleanliness in the premises and appur-

tenances of the milk trade, and particularly of guarding against the well-known liability of milk to take up effluvia existing or arising near it. The order of council having remained inoperative, it is proposed to deal with the matter by a new Act of Parliament, to be administered by the local government board. While cows' milk has thus been recognized by the sanitary law as a carrier of certain of the human contagia, the milk of diseased cows, and more especially of tuberculous cows, continues to be sold with impunity, the alleged communication of tubercular disease from the cow to man being difficult to prove to the satisfaction of the legislature. The want of constant supervision of the slaughter-houses is thought by many to be a serious defect in the sanitary law of the country; and there is no doubt that much flesh of diseased animals (especially the tuberculous) is sold merely as inferior meat.

*Public Health Law of the United States.*—Questions of public health in the United States come under the common law and the statute law. In the larger part of the Union they are subject to the common law only; in a certain number of the States there is statute law; and there has been since 1879 a national board of health and a quarantine law established by Act of Congress. Generally speaking, the public health procedure of the United States suffers from the want of organization. Decisions at common law relate chiefly to nuisances, and to the recovery of damages for loss caused by the same. The first attempt at statute law was an Act of 1866 creating a metropolitan sanitary district and board of health for the city of New York; in 1869 a board of health was created by the State legislature for Massachusetts; the District of Columbia obtained its board of health in 1870; and other States have followed at intervals, so that there are now at least nineteen State boards of health, New York State and Pennsylvania having health boards only for their respective capitals and other individual towns. Besides the municipal boards in those States, there are very few others for towns in the Union, and still fewer for counties. The powers and activity of the boards of health are very various; the Massachusetts board has powers amounting to that of a court, while the function of several of the State boards is hardly more than advisory. The sanitary statutes made by the State legislatures are in some cases very numerous. Wherever questions of quarantine for yellow fever have arisen, as in Louisiana (New Orleans), Georgia, and Alabama, the State board of health has acquired vigour and has enlisted popular support, in the capitals at least; but in most of the States *laissez faire* is the ordinary feeling towards the board and its operations. The medical profession in each State is the most powerful force, and the State medical society is not unfrequently in a semi-official connexion with the sanitary board; on the other hand, it is alleged that the unfortunate sectarian differences in medicine (represented chiefly by homœopathy) have on several occasions prevented the formation of a State board of health, or have tended to paralyse the action of a board already existing. It is a charge also against boards of health, or at least against those in the great political centres, that their efficiency is apt to be impaired by the introduction of irrelevant political considerations in such matters as the making of appointments. The first step towards a national public health law was gained by the Act (approved 3d March 1879) "to prevent the introduction of infectious or contagious diseases into the United States, and to establish a national board of health." The board consists of seven members appointed by the president and of four officials detached from the public departments of State. Its duties are "to obtain information upon all matters affecting the public health, to advise the several departments of the government, the executives of the several States, and the commissioners of the District of Columbia, on all questions submitted to them, or whenever, in the opinion of the board, such advice may tend to the preservation and improvement of the public health." Quarantine was to be a special object of the board's attention, especially the establishment, if possible, of a federal quarantine system which would preserve the legitimate commercial interests of the several States and their seaports. A quarantine law passed in 1879 provides that all vessels coming from any foreign port where contagious or infectious diseases exist shall obtain a bill of health from the consular officer of the United States at the port of sailing. One of the principal functions of the national board of health hitherto has been to institute scientific inquiries into the nature and causation of diseases of national importance, such as malarial fever. Among the acknowledged desiderata in the national sanitary law of the United States are a uniform carrying out of the practice of vaccination—there is no vaccination law in certain States, and in others it is imperfectly applied—and a uniform system of registration of births and deaths. See Bowditch, *Public Hygiene in America, together with a Digest of American Sanitary Law* (by Pickering), Boston, 1877; Billings, Introduction to *Hygiene and Public Health*, edited by Buck (Eng. ed., London), and in the *Transactions of the International Medical Congress*, London, 1880, vol. iv., sect. "Public Health."

*Public Health Law of other Countries.*—In France there is a council of health for each district, composed of medical practitioners, pharmacists, engineers, and other experts, its function being purely advisory with respect to nuisances, unwholesome dwellings, schools, food, drugs, epidemics, and the like. The executive power rests with the prefect (to be carried out by the police), and is often not put in motion even when advice is tendered. In Paris there are two heads of executive, the prefect of the Seine and the prefect of police. The minister of agriculture and commerce is responsible to the chambers. In Prussia there is a certain amount of bureaucratic care of the public health under the ministry for ecclesiastical, educational, and medical affairs. The minister is advised by a scientific commission (*Wissenschaftliche Deputation für das Medicinalwesen*); and there is a subordinate board for each province, and a medical officer for each district or town (*Kreisphysikus*, or *Stadtphysikus*). Numerous offences against the public health are defined in the code, and penalties fixed (see Eulenberg's work, taken from official sources, *Das Medicinalwesen in Preussen*, Berlin, 1874).

2. The lunacy laws have been fully treated of in a special section of the article INSANITY (*q.v.*). By an Act of 1879 habitual drunkards have been placed in a position somewhat analogous to that of lunatics, and there are now existing certain licensed asylums for their detention.

3. The Acts relating to the status of the medical profession are known as the Medical Acts. The principal measure, passed in 1858, created a body of twenty-four, called the general council of medical education and registration; by a subsequent Act the council received a charter of incorporation, so that it might draw up, and become the publisher and proprietor of, a list and description of officinal drugs, which should be called the British Pharmacopœia, and should supersede previous pharmacopœias. The principal duty of the medical council is to keep a register of qualified medical practitioners. The preamble of the Act by which the medical register was created asserts the desirability of those in want of medical aid being able to distinguish qualified from unqualified practitioners; and those whose names are on the register are alone presumably qualified. To be a registered medical practitioner confers a certain positive legal status (right to sue for fees, hold appointments, give certificates, &c.); but there is nothing in the English law to prevent any person whomsoever from practising medicine and taking fees, provided he does not assume misleading titles. Those who are entitled (on payment of five pounds) to have their names inserted in the medical register are graduates in medicine or surgery of the universities of the United Kingdom, licentiates, members, or fellows of the Royal Colleges of Physicians or Surgeons in London, Dublin, and Edinburgh, licentiates or fellows of the Faculty of Physicians and Surgeons of Glasgow, and licentiates of the Apothecaries' Halls of London and Dublin. The council consists of the representatives of those bodies, of six crown nominees, and the president. The medical council possesses certain judicial and executive powers over the names on its register; if, after due inquiry, a registered practitioner be judged by the medical council to have been guilty of infamous conduct in any professional respect, the medical council may, if they see fit, direct their registrar to erase the practitioner's name from the register. The medical council keeps also a register (unpublished) of medical students; whoever has passed a recognized examination in arts, and has forwarded a certificate signed by a teacher of medicine that he has *bona fide* begun the study of medicine, is entitled to have his name entered in the register of students of medicine, with the date of his commencement. The object of the students' register is merely to provide a common and convenient record of the date of commencement of medical study, and, by implication, of the fact that the examination in arts has been passed.

The medical council owes its title of a "council of educa-

tion" to certain powers possessed by it of visiting the examinations of the universities and corporations, and certain ill-defined powers of visiting the medical schools. The council may, if they see fit, report to the privy council any deficiencies that they may have discovered in the teaching or examining, and the privy council may proceed to further steps. But, beyond publishing the reports of their visitations, the medical council do not appear to have had occasion to put the machinery in force. The state has not otherwise interfered to prescribe the subject-matter or the minimum standard of medical education, although there has been at least one unsuccessful attempt by the Government of the day to establish a uniform minimum. By an Act of 1876 parliament has interposed to affirm the principle that women are entitled to become registered practitioners of medicine.

Under the Dentists' Act of 1878 the profession of dentistry acquired a legal status corresponding to that of the medical profession, the general medical council having charge of its register also.

Pharmaceutical chemists are now licensed under an Act passed in 1876; since that date licences are granted only to those who pass either the minor or the major examination of the Pharmaceutical Society of Great Britain, a Pharmacy Act for Ireland (1876) having corresponding provisions.

*The Medical Profession in other Countries.*—In the United States there are usually no restrictions upon the practice of medicine, and in only a few of the States has the medical profession any legal standing. The ordinary medical title is that of doctor of medicine, and that degree is conferred by a large number of institutions after a curriculum of study that varies much in length, and after examinations that are equally various as tests of proficiency. In France the medical profession is divided into two grades: those in the higher grade are all doctors of medicine of the faculties of Paris, Lille, Nancy, Bordeaux, Lyons, or Montpellier; those in the lower grade are *officiers de santé*. In Germany the right to practise is conferred by a state licence granted on passing the *staats-examen*: the examination, which is almost entirely oral and practical, may be passed in stages at any one of the universities in the empire, the professors of anatomy, physiology, and pathological anatomy being practically *ex officio* examiners, while the other examiners are very frequently also professors in the medical faculty. The *staats-examen* is usually passed before the candidate seeks the degree of doctor of medicine; that degree is almost always taken by those who pass the examination for the state licence, and it is usually conferred after a more or less formal examination of the candidate before the medical faculty, and on the approval of his thesis. In Austria, the right to practise is carried by the degree of doctor of medicine; there is no separate state licence, and no examination except that of the medical faculty of the universities (see Billroth's *Lehren and Lernen der medicinischen Wissenschaften*, Berlin, 1876). In most Continental countries there are penalties directed in effect against practising medicine without the state licence, or the university degree equivalent thereto, and in France the law now extends to resident foreign practitioners who have qualified only in their own country. The regulations for the practice of pharmacy in Germany and other Continental countries have long been of a very stringent kind. The training and licensing of midwives is also under state control.

4. Lastly, the state has interposed to restrict the "practice" of anatomy and physiology. By the Anatomy Act of 1832 (amended in 1871) licences are required for schools of anatomy, as well as licences for teachers, "to practise anatomy." Licensed teachers of anatomy are empowered to receive subjects for dissection under certain conditions. The Act is administered by the home office, with a staff of four inspectors of anatomy, one for the metropolis, one for provincial medical schools in England, and one each for Ireland and Scotland. The Act restricting the practice of physiology is the Vivisection Act of 1876; it is intended for the protection of vertebrate animals liable to be employed alive in physiological experiments, and it resorts to a controlling machinery of licence and inspection similar to that of the Anatomy Act, and under the same Government department. (C. C.)

## PART II.—HISTORY.

The history of medicine falls naturally under two heads, or might be conceivably written from two different points of view. It might be a history of the medical profession or a history of medical doctrine,—in other words, the history of medicine in its relation to society or in its relation to science. We shall here deal chiefly with the history of medical knowledge, remembering also that the histories of anatomy, of physiology, and of surgery are dealt with in the articles referring to those subjects. But a still more trenchant limitation is necessary to preserve the unity of the subject. Attention can be given to so much only of the history as is directly antecedent to and leads up to the medical science of modern Europe. For this purpose, the history of medicine must start with the earlier period of Greek civilization.

*Medicine as Portrayed in the Homeric Poems.*—In the state of society pictured by Homer it is clear that medicine has already had a history. We find a distinct and organized profession; we find a system of treatment, especially in regard to injuries, which it must have been the work of long experience to frame; we meet with a nomenclature of parts of the body substantially the same (according to Daremberg) as that employed long afterwards in the writings of Hippocrates; in short, we find a science and an organization which, however imperfect as compared with those of later times, are yet very far from being in their beginning. The Homeric heroes themselves are represented as having considerable skill in surgery, and as able to attend to ordinary wounds and injuries, but there is also a professional class, represented by Machaon and Podalirius, the two sons of Asclepius, who are treated with great respect. It would appear, too, from the *Æthiopis* of Arctinus (quoted by Welcker and Haeser) that the duties of these two were not precisely the same. Machaon's task was more especially to heal injuries, while Podalirius had received from his father the gift of "recognizing what was not visible to the eye, and tending what could not be healed." In other words, a rough indication is seen of the separation of medicine and surgery. Asclepius appears in Homer as a Thessalian king, not as a god, though in later times divine honours were paid to him. There is no sign in the Homeric poems of the subordination of medicine to religion which is seen in ancient Egypt and India, nor are priests charged, as they were in those countries, with medical functions,—all circumstances which throw grave doubts on the commonly received opinion that medicine derived its origin in all countries from religious observances.

Although the actual organization of medicine among the Homeric Greeks was thus quite distinct from religion, the worship of Asclepius (or Æsculapius) as the god of healing demands some notice. This cult spread very widely among the Greeks; it had great civil importance, and lasted even into Christian times; but there is no reason to attribute to it any special connexion with the development of the science or profession of medicine. Sick persons repaired, or were conveyed, to the temples of Asclepius in order to be healed, just as in modern times relief is sought by a devotional pilgrimage or from the waters of some sacred spring, and then as now the healing influence was sometimes sought by deputy. The sick person, or his representative, after ablution, prayer, and sacrifice, was made to sleep on the hide of the sacrificed animal, or at the feet of the statue of the god, while sacred rites were performed. In his sleep (incubatio, ἐγκοί-

μησις) the appropriate remedy was indicated by a dream. Moral or dietetic remedies were more often prescribed than drugs. The record of the cure was inscribed on the columns or walls of the temple; and it has been thought that in this way was introduced the custom of "recording cases," and that the physicians of the Hippocratic school thus learnt to accumulate clinical experience. But the priests of Asclepius were not physicians. Although the latter were often called Asclepiads, this was in the first place to indicate their real or supposed descent from Asclepius, and in the second place as a complimentary title. No medical writing of antiquity speaks of the worship of Asclepius in such a way as to imply any connexion with the ordinary art of healing. The two systems appear to have existed side by side, but to have been distinct, and if they were ever united it must have been before the times of which we have any record. The theory of a development of Greek medicine from the rites of Asclepius, though defended by eminent names, must accordingly be rejected.

*Development of Medicine in Greece.*—It is only from non-medical writers that anything is known of the development of medicine in Greece before the age of Hippocrates. The elaborate collections made by Daremberg of medical notices in the poets and historians illustrate the relations of the profession to society, but do little to prepare us for the Hippocratic period. Nor is much importance to be attached to the influence of the philosophical sects on medicine except as regards the school of Pythagoras. That philosopher and several of his successors were physicians, but we do not know in what relation they stood to later medical schools. We must therefore hasten onward to the age of Pericles, in which Hippocrates, already called "the Great," was in medicine as complete a representative of the highest efforts of the Greek intellect as were his contemporaries the great philosophers, orators, and tragedians. The medical art as we now practise it, the character of the physician as we now understand it, both date for us from Hippocrates. The justification of this statement is found in the literary collection of writings known by his name. Of these certainly many are falsely ascribed to the historical Hippocrates of Cos; others are almost as certainly rightly so ascribed; others again are clearly works of his school, whether from his hand or not. But which are to be regarded as the "genuine works" is still uncertain, and authorities are conflicting. There are clearly two schools represented in the collection,—that of Cnidus in a small proportion, and that of Cos in far the larger number of the works. The latter was that to which Hippocrates belonged, and where he gave instruction; and accordingly it may be taken that works of this school, when not obviously of a different date, are Hippocratic in doctrine if not in actual authorship.

*Hippocratic Medicine.*—The first grand characteristic of Hippocratic medicine is the high conception of the duties and status of the physician, shown in the celebrated "Oath of Hippocrates" and elsewhere,—equally free from the mysticism of a priesthood and the vulgar pretensions of a mercenary craft. So matured a professional sentiment may perhaps have been more the growth of time and organization than the work of an individual genius, but certainly corresponds with the character universally attributed to Hippocrates himself. The second great quality is the singular artistic skill and balance with which the Hippocratic physician used such materials and tools as he possessed. Here we recognize the true Greek σωφροσύνη. But this artistic completeness was closely connected with the third cardinal virtue of Hippocratic medicine,—the clear recognition of disease as being equally with life a process governed by what we should now call natural laws, which could be known by observation, and which indicated the spontaneous and normal direction of recovery, by following which alone could the physician succeed. In the fourth place, these views of the "natural history of disease" (in modern language) led to habits of minute observation and accurate interpretation of symptoms, in which the Hippocratic school was unrivalled in antiquity, and has been the model for all succeeding ages, so that even in these days, with our enormous advances in knowledge, the true method of clinical medicine may be said to be the method of Hippocrates.

The actual science of the Hippocratic school was of course very limited. In anatomy and physiology little advance had been made, and so of pathology in the sense of an explanation of morbid processes or knowledge of diseased structures there could be very little. The most valuable intellectual possession was a large mass of recorded observations in individual cases and epidemics of disease. Whether these observations were systematic or individual, and how they were recorded, are points of which we are quite ignorant, as the theory that the votive tablets in the temples supplied such materials must be abandoned.

Though the Hippocratic medicine was so largely founded on observation, it would be an error to suppose that dogma or theory had no place. The dominating theory of disease was the *humoral*, which has never since ceased to influence medical thought and practice. According to this celebrated theory, the body contains four humours,—blood, phlegm, yellow bile, and black bile, a right proportion and mixture of which constitute health; improper proportions or irregular distribution, disease. It is doubtful whether the treatise in which this theory is fully expounded (περὶ φύσιος ἀνθρώπου) is as old as Hippocrates himself; but it was regarded as a Hippocratic doctrine, and, when taken up and expanded by Galen, its terms not only became the common property of the profession, but passed into general literature and common language. Another Hippocratic doctrine, the influence of which is not even yet exhausted, is that of the healing power of nature. Not that Hippocrates taught, as he was afterwards reproached with teaching, that nature is sufficient for the cure of diseases; for he held strongly the efficacy of art. But he recognized, at least in acute diseases, a natural process which the humours went through,—being first of all *crude*, then passing through *coction* or digestion, and finally being expelled by resolution or *crisis* through one of the natural channels of the body. The duty of the physician was to foresee these changes, "to assist or not to hinder them," so that "the sick man might conquer the disease with the help of the physician." The times at which crises were to be expected were naturally looked for with anxiety; and it was a cardinal point in the Hippocratic system to foretell them with precision. Hippocrates, influenced as is thought by the Pythagorean doctrines of number, taught that they were to be expected on days fixed by certain numerical rules, in some cases on odd, in others on even numbers,—the celebrated doctrine of "critical days." This false precision can have had no practical value, but may have enforced habits of minute observation. It follows from what has been said that *prognosis*, or the art of foretelling the course and event of the disease, was a strong point with the Hippocratic physicians. In this they have perhaps never been excelled. Diagnosis, or recognition of the disease, must have been necessarily imperfect, when no scientific nosology, or system of disease, existed, and the knowledge of anatomy was quite inadequate to allow of a precise determination of the seat of disease; but symptoms were no doubt observed and interpreted skilfully. The pulse is not spoken of in any of the works now attributed to Hippocrates himself, though it is mentioned in other works of the collection.

In the treatment of disease, the Hippocratic school attached great importance to diet, the variations necessary in different diseases being minutely defined. Medicines were regarded as of secondary importance, but not neglected, two hundred and sixty-five drugs being mentioned at different places in the Hippocratic works. Blood-letting was known, but not greatly practised. The highest importance was attached to applying all remedies at the right moment, and the general principle enforced of making all influences—internal and external—co-operate for the relief of the patient. The principles of treatment just mentioned apply more especially to the cure of acute diseases; but they are the most salient characteristics of the Hippocratic school. In chronic cases diet, exercise, and natural methods were chiefly relied upon.

The school of Cnidus, as distinguished from that of Cos, of which Hippocrates is the representative, appears to have differed in attaching more importance to the differences of special diseases, and to have made more use of drugs. A treatise on the diseases of women, contained in the Hippocratic collection, and of remarkable practical value, is attributed to this school.

The above sketch of Hippocratic medicine will make it less necessary to dwell upon the details relating to subsequent medical schools or sects in ancient times. The general conception of the physician's aim and task remained the same, though, as knowledge increased, there was much divergence both in theory and practice,—even opposing schools were found to be developing some part of the Hippocratic system. Direct opponents or repudiators of the authority of Hippocrates were rare, all generally appealing to his authority. But, insensibly, the least valuable part of the Hippocratic work, the theory, was made permanent; the most valuable, the practical, neglected.

*Post-Hippocratic Medicine.*—After Hippocrates the progress of medicine in Greece does not call for any special remark in such a sketch as this, but mention must be made of one great name. Though none of Aristotle's writings are strictly medical, he has by his researches in anatomy and physiology contributed greatly to the progress of medicine. It should also be remembered that he was of an Asclepiad family, and received that partly medical education which was traditional in such families, and also himself is said to have practised medicine as an amateur. Moreover, his works on natural history doubtless furthered the progress among the Greeks of sciences tributary to medicine, though the only specimens of such works which have come down to us from the Peripatetic school are those of Theophrastus, who may be considered the founder of the scientific study of botany. Among his encyclopædic writings were some on medical subjects, of which fragments only have been preserved. The Peripatetic school may have been more favourable to the development of medicine, as of other departments of natural knowledge, than any other; but there is no evidence that any of the philosophical schools had important influence on the progress of medicine. The fruit of Aristotle's teaching and example was seen later on in the schools of Alexandria.

The century after the death of Hippocrates is a time almost blank in medical annals. It is probable that the science, like others, shared in the general intellectual decline of Greece after the Macedonian supremacy; but the works of physicians of the period are almost entirely lost, and were so even in the time of Galen. Galen classes them all as of the dogmatic school; but, whatever may have been their characteristics, they are of no importance in the history of the science.

*Alexandrian School of Medicine.*—The dispersion of Greek science and intellectual activity through the world by the conquests of Alexander and his successors led to the formation of more than one learned centre, in which medicine among other sciences was represented. Pergamum was early distinguished for its medical school; but in this as in other respects its reputation was ultimately effaced by the more brilliant fame of Alexandria. It is here that the real continuation and development of Hippocratic medicine can be traced.

In one department the Alexandrian school rapidly surpassed its Greek original, namely, in the study of anatomy. The dissection of the human body, of which some doubtful traces or hints only are found in Greek times, was assiduously carried out, being favoured or even suggested perhaps by the Egyptian custom of disembowelling and embalming the bodies of the dead. There is no doubt that the organs were also examined by opening the bodies of living persons,—criminals condemned to death being given over to the anatomists for this purpose.

Two eminent names stand in the first rank as leaders of the two earliest schools of medicine which arose in Alexandria, Herophilus and Erasistratus.

Herophilus was a Greek of Chalcedon, a pupil of the schools both of Cos and of Cnidus. He was especially noted for his profound researches in anatomy (see vol. i. p. 802), and in the knowledge and practice of medicine he appears to have been equally renowned. He professed himself a close adherent of Hippocrates, and adopted his theory of the humours. He also made extensive use of drugs, and of bleeding. The reputation of Herophilus is attested by the fact that four considerable physicians wrote works about him and his writings, and he is further spoken of with the highest respect by Galen and Celsus. By the general voice of the medical world of antiquity he was placed only second to Hippocrates.

Erasistratus was the contemporary and rival of Herophilus. Little is known of his life, except that he spent some time at the court of Seleucus Nicator at Antioch before coming to Alexandria, and that he cultivated anatomy late in life, after he had taken up his abode in the latter city. His numerous works are also almost entirely lost, fragments only being preserved by Galen and others. Erasistratus, instead of following Hippocrates as Herophilus did, depreciated him, and seems to have been rather aggressive and independent in his views. He appears to have leaned to mechanical explanations of the symptoms of disease, as was especially the case with inflammation, of which he gave the first rational, though necessarily inadequate, theory.

The two schools composed of the followers of Herophilus and Erasistratus respectively long divided between them the medical world of Alexandria. The names of many prominent members of both sects have been preserved, but it would be useless to repeat them. The Herophilists still reverenced the memory of Hippocrates, and wrote numerous commentaries on his works. They produced many eminent anatomists, but in the end seem to have become lost in theoretical subtleties, and to have maintained too high a standard of literary cultivation. The school of Erasistratus was less distinguished in anatomy than that of Herophilus, but paid more attention to the special symptoms of diseases, and employed a great variety of drugs. It was longer-lived than that of Herophilus, for it still numbered many adherents in the 2d century after Christ, a century after the latter had become extinct.

The Erasistrateans paved the way for what was in some respects the most important school which Alexandria produced, that known as the empiric, which, though it recognized no master by name, may be considered to have been founded by Philinus of Cos (280 B.C.), a pupil of Herophilus; but Serapion, a great name in antiquity, and Glaucias of Tarentum, who traced the empirical doctrine

back to the writings of Hippocrates, are also named among its founders. The most striking peculiarity of the empirics was that they rejected anatomy, regarding it as useless to inquire into the causes of things, and thus, as they contended, being the more minute in their observation of the actual phenomena of disease. They professed that their whole practice was based upon experience, to which word they gave a special meaning. Three sources, and three only, could experience draw from:—observation, history (*i.e.*, recorded observation), and judgment by analogy. These three bases of knowledge were known as the "tripod" of the empirics. It should not, however, be forgotten that the empirics read and industriously commented on the works of Hippocrates. They were extremely successful in practical matters, especially in surgery and in the use of drugs, and a large part of the routine knowledge of diseases and remedies which became traditional in the times of the Roman empire is believed to have been derived from them. In the 2d century the school became closely connected with the philosophical sect of the Sceptics, whose leader, Sextus, was an empirical physician. It lived and flourished far beyond this time, when transplanted to Rome, not less than in its native Alexandria, and appears to be recognizable even up to the beginning of the Middle Ages.

If we look at the work of the Alexandrian schools in medicine as a whole, we must admit that the progress made was great and permanent. The greatest service rendered to medicine was undoubtedly the systematic study of anatomy. It is clear that the knowledge of function (physiology) did not by any means keep pace with the knowledge of structure, and this was probably the reason why the important sect of the empirics were able entirely to dispense with anatomical knowledge. The doctrines of Hippocrates, though lightly thought of by the Erasistrateans, still were no doubt very widely accepted, but the practice of the Hippocratic school had been greatly improved in almost every department,—surgery and obstetrics being probably those in which the Alexandrian practitioners could compare most favourably with those of modern times. We have now to trace the fortunes of this body of medical doctrine and practice when transplanted to Rome, and ultimately to the whole Roman world.

*Roman Medicine.*—The Romans cannot be said to have at any time originated or possessed an independent school of medicine. They had from early times a very complicated system of superstitious medicine, or religion, related to disease and the cure of disease, borrowed, as is thought, from the Etruscans; and, though the saying of Pliny that the Roman people got on for six hundred years without doctors was doubtless an exaggeration, and not, literally speaking, exact, it must be accepted for the broad truth which it contains. When a medical profession appears, it is, so far as we are able to trace it, as an importation from Greece.

The first Greek physician whose name is preserved as having migrated to Rome was Archagathus, who came over from the Peloponnesus in 218 B.C.; but there were probably others before him. When Greece was made a Roman province, the number of such physicians who sought their fortunes in Rome must have been very large. The bitter words of M. Porcius Cato, who disliked them as he did other representatives of Greek culture, are evidence of this. The most eminent of these earlier Greek physicians at Rome was Asclepiades, the friend of Cicero (born 124 B.C. at Prusa in Bithynia). He came to Rome as a young man, and soon became distinguished both for his medical skill and his oratorical power. He introduced a system which, so far as we know, was his own, though founded upon the Epicurean philosophical creed; on the practical side it conformed pretty closely to the Stoic rule of life, thus adapting itself to the leanings of the better stamp of Romans in the later times of the republic. According to Asclepiades all diseases depended upon alterations in the size, number, arrangement, or movement of the "atoms," of which, according to the doctrine of Epicurus, the body consisted. These atoms were united into passages (πόροι) through which the juices of the body were conveyed. This doctrine, of which the developments need not further be followed, was important chiefly in so far that it was perfectly distinct from, and opposed to, the humoral pathology of Hippocrates. In the treatment of disease Asclepiades attached most importance to diet, exercise, passive movements or frictions, and the external use of cold water,—in short, to a modified athletic training. He rejected the *vis medicatrix naturæ*, pointing out that nature in many cases not only did not help but marred the cure. His knowledge of disease and surgical skill were, as appears from the accounts given by Celsus and Cœlius Aurelianus, very considerable. Asclepiades had many pupils, who adhered more or less closely to his doctrines, but it was especially one of them, Themison, who gave permanence to the teachings of his master by framing out of them, with some modifications, a new system of medical doctrine, and founding on this basis a school which lasted for some centuries in successful rivalry with the Hippocratic tradition, which, as we have seen, was up to that time the prevailing influence in medicine.

This system was known as methodism, its adherents as the methodici or methodists. Its main principles were that it was useless to consider the causes of a disease, or even the organ affected by the disease, and that it was sufficient to know what was common to all diseases, viz., their common qualities (communitates, κοινότητες). Of these there were three possible forms—(1) relaxation, (2) contraction of the minute passages or πόροι, and (3) a mixed state, partly lax, partly constricted. The signs of these morbid states were to be found in the general constitution of the body, especially in the excretions. Besides this it was important only to consider whether the disease was acute or chronic, whether it was increasing, declining, or stationary. Treatment of disease was directed not to any special organ, nor to producing the crises and critical discharges of the Hippocratic school, but to correcting the morbid common condition or "community," relaxing the body if it was constricted, causing contraction if it was too lax, and in the "mixed state" acting according to the predominant condition. This simple rule of treatment was the system or "method" from which the school took its name.

The methodists agreed with the empirics in one point, in their contempt for anatomy; but, strictly speaking, they were dogmatists, though with a dogma different from that of the Hippocratic school. Besides Themison, its systematic founder, the school boasted many physicians eminent in their day, among whom Thessalus of Tralles, a half-educated and boastful pretender, was one of the most popular. He reversed the Hippocratic maxim "art is long," promising his scholars to teach them the whole of medicine in six months, and had inscribed upon his tomb ἰατρονίκης, as being superior to all living and bygone physicians.

In the 2d century a much greater name appears among the methodists, that of Soranus of Ephesus, a physician mentioned with praise even by Tertullian and Augustine, who practised at Rome in the reigns of Trajan and Hadrian. Soranus is known by a work, still extant in the Greek original, on the diseases of women, and also by the Latin work of Cœlius Aurelianus, three centuries later, on acute and chronic diseases, which is based upon, if not, as some think, an actual translation of, the chief

work of Soranus, and which is the principal source of our knowledge of the methodic school. The work on diseases of women is the only complete work on that subject which has come down to us from antiquity, and shows remarkable fulness of practical knowledge in relation to its subject. It is notable that an important instrument of research, the speculum, which has been reinvented in modern times, was used by Soranus; and specimens of still earlier date, showing great mechanical perfection, have been found among the ruins of Pompeii. The work on acute and chronic diseases is also full of practical knowledge, but penetrated with the theories of the methodists.

The methodic school lasted certainly for some centuries, and influenced the revival of medical science in the Middle Ages, though overshadowed by the greater reputation of Galen. It was the first definite product of Greek medicine on Roman soil, but was destined to be followed by others, which kept up a more or less successful rivalry with it, and with the Hippocratic tradition.

The so-called pneumatic school was founded by Athenæus, in the 1st century after Christ. According to its doctrines the normal as well as diseased actions of the body were to be referred to the operation of the pneuma or universal soul. This doctrine, crudely transferred from philosophical speculation, was intended to reconcile the humoral (or Hippocratic) and solidist (or methodic) schools; but the methodists seem to have claimed Athenæus as one of themselves.

The conflicts of the opposing schools, and the obvious deficiencies of each, led many physicians to try and combine the valuable parts of each system, and to call themselves eclectics. Among these were found many of the most eminent physicians of Græco-Roman times. It may be sufficient to name Rufus of Ephesus, and Archigenes, who is mentioned by Juvenal.

Although no system or important doctrine of medicine was originated by the Roman intellect, and though the practice of the profession was probably almost entirely in the hands of the Greeks, the most complete picture which we have of medical thought and activity in Roman times is due to a Latin pen, and to one who was, in all probability, not a physician. A. Cornelius Celsus, a Roman patrician, who lived probably in the first century, appears to have studied medicine as a branch of general knowledge. Whether he was a practising physician or not has been a matter of controversy. The conclusion supported by most evidence seems to be that he practised on his friends and dependants, but not as a remunerative profession. His well-known work, *De Medicina*, was one of a series of treatises intended to embrace all knowledge proper for a man of the world. It was not meant for the physicians, and was certainly little read by them, as Celsus is quoted by no medical writer, and when referred to by Pliny is spoken of as an author, not a physician. There is no doubt that his work is chiefly a compilation; and Daremberg, with other scholars, has traced a large number of passages of the Latin text to the Greek originals from which they were translated. In the description of surgical operations the vagueness of the language seems sometimes to show that the author had not performed such himself; but in other parts, and especially in his historical introduction, he speaks with more confidence; and everywhere he compares and criticizes with learning and judgment. The whole body of medical literature belonging to the Hippocratic and Alexandrian times is ably summarized, and a knowledge of the state of medical science up to and during the times of the author is thus conveyed to us which can be obtained from no other source. The work of Celsus is thus for us only second in importance to the Hippocratic writings and the works of Galen; but it is valuable rather as a part of the history of medicine than as the subject of that history. It forms no link in the general chain of medical tradition, for the simple reason that the influence of Celsus (putting aside a few scanty allusions in mediæval times) commenced in the 15th century, when his works were first discovered in manuscript or committed to the press. Since then, however, he has been almost up to our own times the most popular and widely-read of all medical classics, partly for the qualities already indicated, partly because he was one of the few of those classics accessible to readers of Latin, and partly also because of the purity and classical perfection of his language.

Of Pliny, another encyclopædic writer, a few words must be said, though he was not a physician. In his *Natural History* we find as complete a summary of the popular medicine of his time as Celsus gives of the scientific medicine. Pliny disliked doctors, and lost no opportunity of depreciating regular medicine; nevertheless he has left many quotations from, and many details about, medical authors which are of the highest value. He is useful to us for what he wrote about the history of medicine, not for what he contributed. Like Celsus, he had little influence on succeeding medical literature or practice.

We now come to the writer who, above all others, gathered up into himself the divergent and scattered threads of ancient medicine, and out of whom again the greater part of modern European medicine has flowed. Galen (see vol. i. 803 and x. 23) was a man furnished with all the anatomical, medical, and philosophical knowledge of his time; he had studied all kinds of natural curiosities, and had stood in near relation to important political events; he possessed enormous industry, great practical sagacity, and unbounded literary fluency. He had, in fact, every quality necessary for an encyclopædic writer, or even for a literary and professional autocrat. He found the medical profession of his time split up into a number of sects, medical science confounded under a multitude of dogmatic systems, the social status and moral integrity of physicians degraded. He appears to have made it his object to reform these evils, to reconcile scientific acquirements and practical skill, to bring back the unity of medicine as it had been understood by Hippocrates, and at the same time to raise the dignity of medical practitioners.

Galen was as devoted to anatomical and, so far as then understood, physiological research as to practical medicine. He worked enthusiastically at dissection, though, the liberty of the Alexandrian schools no longer existing, he could dissect only animals, not the human body. In his anatomical studies Galen had a twofold object,—a philosophical, to show the wisdom of the Creator in making everything fit to serve its purpose, and a practical, to aid the diagnosis, or recognition, of disease. The first led him into a teleological system so minute and overstrained as to defeat its own end; the second was successfully attained by giving greater precision and certainty to medical and surgical practice in difficult cases. His general physiology was essentially founded upon the Hippocratic theory of the four elements, with which he combined the notion of spirit (pneuma) penetrating all parts, and mingled with the humours in different proportions. It was on this field that he most vehemently attacked the prevailing atomistic and materialistic views of the methodic school, and his conception of the pneuma became in some respects half metaphysical. His own researches in special branches of physiology were important, but do not strictly belong to our present subject.

The application of physiology to the explanation of diseases, and thus to practice, was chiefly by the theory of the temperaments or mixtures which Galen founded upon

the Hippocratic doctrine of humours, but developed with marvellous and fatal ingenuity. The normal condition or temperament of the body depended upon a proper mixture or proportion of the four elements—hot, cold, wet, and dry. From faulty proportions of the same arose the *intemperies* ("distempers"), which, though not diseases, were the occasions of disease. Equal importance attached to faulty mixtures or dyscrasiæ of the blood. By a combination of these morbid predispositions with the action of deleterious influences from without all diseases were produced. Galen showed extreme ingenuity in explaining all symptoms and all diseases on his system. No phenomenon was without a name, no problem without a solution. And, though it was precisely in his fine-spun subtlety that he departed farthest from scientific method and practical utility, it was this very quality which seems in the end to have secured his popularity and established his pre-eminence in the medical world.

Galen's use of drugs was influenced largely by the same theories. In drugs were to be recognized the same elementary qualities—hot, cold, moist, dry, &c.—as in the human body; and, on the principle of curing by contraries, the use of one or other was indicated. The writings of Galen contain less of simple objective observation than those of several other ancient physicians, all being swept into the current of dogmatic exposition. But there is enough to show the thoroughness and extent of his practical knowledge. Unfortunately it was neither this nor his zeal for research that chiefly won him followers, but the completeness of his theoretical explanations, which fell in with the mental habits of succeeding centuries, and were such as have flattered the intellectual indolence of all ages. But the reputation of Galen grew slowly; he does not appear to have enjoyed any pre-eminence over other physicians of his time, to most of whom he was strongly opposed in opinion. In the next generation he began to be esteemed only as a philosopher; gradually his system was implicitly accepted, and it enjoyed a great though not exclusive predominance till the fall of Roman civilization. When the Arabs possessed themselves of the scattered remains of Greek culture, the works of Galen were more highly esteemed than any others except those of Aristotle. Through the Arabs the Galenical system found its way back again to Western Europe. Even when Arabian medicine gave way before the direct teaching of the Greek authors rescued from neglect, the authority of Galen was increased instead of being diminished; and he assumed a position of autocracy in medical science which was only slowly undermined by the growth of modern science in the 17th and 18th centuries.

But the history of medicine in Roman times is by no means the same thing as the history of the fate of the works of Galen. For some centuries the methodic school was popular at Rome, and produced one physician, Cœlius Aurelianus, who must be pronounced, next to Celsus, the most considerable of the Latin medical writers. His date was in all probability the end of the 4th or beginning of the 5th century. The works bearing his name are, as has been said, entirely based upon the Greek of Soranus, but are important both because their Greek originals are lost, and because they are evidence of the state of medical practice in his own time. The popularity of Cœlius is evidenced by the fact that in the 6th century an abridgment of his larger work was recommended by Cassiodorus to the Benedictine monks for the study of medicine.

Before quitting this period the name of Aretæus of Cappadocia must be mentioned. So little is known about him that even his date cannot be fixed more closely than as being between the second half of the 1st century and the beginning of the 3d. His works have been much admired for the purity of the Greek style, and his accurate descriptions of disease; but, as he quotes no medical author, and is quoted by none before Alexander of Aphrodisias at the beginning of the 3d century, it is clear that he belonged to no school and founded none, and thus his position in the chain of medical tradition is quite uncertain. Alexander of Aphrodisias, who lived and wrote at Athens in the time of Septimius Severus, is best known by his commentaries on Aristotle, but also wrote a treatise on fevers, still extant.

*Ancient Medicine after Galen.*—The Byzantine school of medicine, which closely corresponds to the Byzantine literary and historical schools, followed closely in Galen's footsteps, and its writers were chiefly compilers and encyclopædists. The earliest is Oribasius (326-403), whose date and position are fixed by his being the friend and court physician of Julian the Apostate. He was a Greek of Pergamum, educated in Alexandria, and long resident in Byzantium. His great work Συναγωγαὶ ἰατρικαί, of which only about one-third has been preserved, was a medical encyclopædia founded on extracts from Hippocrates, Galen, Dioscorides, and certain Greek writers who are otherwise very imperfectly known. The work is thus one of great historical value but of no originality. The next name which requires to be mentioned is that of Aetius (550 A.D.), a compiler who closely followed Oribasius, but with inferior powers, and whose work also has an historical but no original value. A higher rank among medical writers is assigned to Alexander of Tralles (525-605), whose doctrine was that of an eclectic. His practical and therapeutical rules are evidently the fruit of his own experience, though it would be difficult to attribute to him any decided advance in medical knowledge. But the most prominent figure in Byzantine medicine is that of Paul of Ægina (Paulus Ægineta), who lived probably in the early part of the 7th century. His skill, especially in surgery, must have been considerable, and his Ἰατρικά gives a very complete picture of the achievements of the Greeks in this department. Another work, on obstetrics, now lost, was equally famous, and procured for him, among the Arabs, the name of "the Obstetrician." His reputation lasted through the Middle Ages, and was not less in the Arabian schools than in the West. In this respect Paulus is a most important influence in the development of medicine. His great work on surgery was early translated into Arabic, and became the foundation of the surgery of Abulcasis, which in turn (to anticipate) was one of the chief sources of surgical knowledge to Europe in the Middle Ages. The succeeding period of Byzantine history was so little favourable to science that no name worthy of note occurs again (though many medical works of this period are still extant) till the 13th century, when we meet with a group of writers;—Demetrius Pepagomenus, Nicolaus Myrepsus, and Johannes, called Actuarius, who flourished under the protection of the Palæologi. The work of the last has some independent merit; but all are interesting as showing a fusion of Greek and Arabian medicine, the latter having begun to exercise even in the 11th century a reflex influence on the schools of Byzantium. Something was borrowed even from the school of Salerno, and thus the close of Byzantine medicine is brought into connexion with the dawn of science in modern Europe.

In the West the period after Galen affords little evidence of anything but a gradual though unvarying decline in Roman medicine. Cœlius Aurelianus, already referred to as the follower of Soranus, must be mentioned as showing the persistence of the methodic school. An abridgment of one of his writings, with the title of *Aurelius*, became the most popular of all Latin medical works. As a writer he

was worthy of a better period of medical literature. Little else was produced in these times but compilations, of the most meagre kind, chiefly of the nature of herbals, or domestic receipt-books; among the authors of which it may be sufficient to name Serenus Sammonicus (3d century), Gargilius Martialis (3d century), and Marcellus Empiricus (5th century). Certain compilations still extant bear the falsely-assumed names of eminent writers, such as Pliny and Hippocrates. A writer with the (perhaps assumed) name of Apuleius Platonicus produced a herbal which held its ground till the 15th century at least, and was in the 9th translated into Anglo-Saxon. These poor compilations, together with Latin translations of certain works of Galen and Hippocrates, formed a medical literature, meagre and unprogressive indeed, but of which a great part survived through the Middle Ages till the discovery of printing and revival of learning. It is important to remember that this obscure stream of tradition flowed on, only partially affected by the influx of Arabian, or even the early revival of purer classical learning.

*Arabian Medicine.*—The rise of the Mohammedan empire, which influenced Europe so deeply both politically and intellectually, made its mark also in the history of medicine. As in the parallel case of the Roman conquest of Greece, the superior culture of the conquered race asserted its supremacy over their Arab conquerors. After the Mohammedan conquests became consolidated, and learning began to flourish, schools of medicine, often connected with hospitals and schools of pharmacy, arose in all the chief seats of Moslem power. At Damascus Greek medicine was zealously cultivated with the aid of Jewish and Christian teachers. In Baghdad, under the rule of Hárún el Rashíd and his successors, a still more flourishing school arose, where numerous translations of Greek medical works were made. The names of Mesua, or Yaḥyá ibn Másawaih (*ob.* 243 A.H., 857–8 A.D.), celebrated for his knowledge of drugs, and Honein ibn Isḥak el 'Ibádí (*ob.* 873) or Joannitius, the translator and commentator of Hippocrates and Galen, belong to this period. Certain writings of Joannitius, translated into Latin, were popular in the Middle Ages in Europe, and were printed in the 16th century. At the same time the Arabs became acquainted with Indian medicine, and Indian physicians lived at the court of Baghdad. The Islamite rulers in Spain were not long behind those of the East in encouraging learning and medical science, and developed culture to a still higher degree of perfection. In that country much was due to the Jews, who had already established schools in places which were afterwards the seats of Moslem dominion. From the 10th to the 13th century was the brilliant period of Arabian medicine in Spain.[1]

The classical period of Arabian medicine begins with Rhazes (Abú Bakr Mohammed ibn Zakaríyá el-Rází, 313 A.H., 925–26 A.D.), a native of Ray in the province of Dailam (Persia), who practised with distinction at Baghdad; he followed the doctrines of Galen, but learnt much from Hippocrates. He was the first of the Arabs to treat medicine in a comprehensive and encyclopædic manner, surpassing probably in voluminousness Galen himself, though but a small proportion of his works are extant. Rhazes is deservedly remembered as having first described small-pox and measles in an accurate manner. Haly, *i.e.*, 'Alí ibn el-'Abbás (*ob.* 994), a Persian, wrote a medical text-book, known as the "Royal Book," which was the standard authority among the Arabs up to the time of Avicenna, and was more than once translated into Latin and printed. Other writers of this century need not be mentioned here; but the next, the 11th century, is given as the probable though uncertain date of a writer who had a great influence on European medicine, Mesua the younger of Damascus, whose personality is obscure, and of whose very existence some historians have doubted, thinking that the name was assumed by some mediæval Latin writer. The work *De Simplicibus*, which bears his name, was for centuries a standard authority on what would now be called materia medica, was printed in twenty-six editions in the 15th century and later, and was used in the formation of the first London pharmacopœia, issued by the College of Physicians in the reign of James I. Either to the 10th or the 11th century must be referred the name of another Arabian physician who has also attained the position of a classic, Abu'l Kásim, or Abulcasis, of El-Zahra, near Cordova in Spain. His great work, *Alttaṣríf*, a medical encyclopædia, is chiefly valued for its surgical portion (already mentioned), which was translated into Latin in the 12th century, and was for some centuries a standard if not the standard authority on surgery in Europe. Among his own countrymen the fame and position of Abulcasis were soon eclipsed by the greater name of Avicenna (Ibn Síná).

Avicenna (see vol. iii. p. 152 *sq.*) has always been regarded as the chief representative of Arabian medicine. He wrote on philosophy also, and in both subjects acquired the highest reputation through the whole of Eastern Islam. In Mohammedan Spain he was less regarded, but in Europe his works even eclipsed and superseded those of Hippocrates and Galen. His style and expository power are highly praised, but the subject-matter shows little originality. The work by which he is chiefly known, the celebrated "canon," is an encyclopædia of medical and surgical knowledge, founded upon Galen, Aristotle, the later Greek physicians, and the earlier Arabian writers, singularly complete and systematic, but is thought not to show the practical experience of its author. As in the case of Galen, the formal and encyclopædic character of Avicenna's works was the chief cause of his popularity and ascendency, though in modern times these very qualities in a scientific or medical writer would rather cause him to become more speedily antiquated.

In the long list of Arabian medical writers none can here be mentioned except the great names of the Hispano-Moorish school, a school both philosophically and medically antagonistic to that of Avicenna. Of these the earliest is Avenzoar, or Abumeron, that is, Abú Merwán 'Abd el-Malik Ibn Zohr (1113–62), a member of a family which gave several distinguished members to the medical profession. His chief work, *Al-Teysîr* (facilitatio), is thought to show more practical experience than the writings of Avicenna, and to be less based upon dialectical subtleties. It was translated into Latin, and more than once printed, as were some of his lesser works, which thus formed a part of the contribution made by the Arabians to European medicine. His friend and pupil AVERROES of Cordova (*q.v.*), so well known for his philosophical writings, was also an author in medical subjects, and as such widely read in Latin. The famous Rabbi MAIMONIDES (*q.v.*) closes for us the roll of medical writers of the Arabian school. His works exist chiefly in the original Arabic or in Hebrew translations; only some smaller treatises have been translated into Latin, so that no definite opinion can be formed as to their medical value. But, so far as is known, the independent and rationalistic spirit which the two last-named writers showed in philosophy did not lead them to take any original point of view in medicine.

The works of the Arabian medical writers who have now been mentioned form a very small fraction of the existing literature. Three hundred medical writers in

[1] See Dozy, *Cat. Cod. Or. Lug. Bat.*, ii. 296.

Arabic are enumerated by Wüstenfeld, and other historians have enlarged the list (Haeser), but only three have been printed in the original; a certain number more are known through old Latin translations, and the great majority still exist in manuscript. It is thus evident that the circumstance of having been translated (which may have been in some cases almost an accident) is what has chiefly determined the influence of particular writers on Western medicine. But it is improbable that further research will alter the general estimate of the value of Arabian medicine. There can be no doubt that it was in the main Greek medicine, modified to suit other climates, habits, and national tastes, and with some important additions from Oriental sources. The greater part is taken from Hippocrates, Galen, Dioscorides, and later Greek writers. The Latin medical writers were necessarily unknown to the Arabs; and this was partly the cause that even in Europe Galenic medicine assumed such a preponderance, the methodic school and Celsus being forgotten or neglected. In anatomy and physiology the Arabians distinctly went back; in surgery they showed no advance upon the Greeks; in practical medicine nothing new can be traced, except the description of certain diseases (*e.g.*, small-pox and measles) unknown or imperfectly known to the Greeks; the only real advance was in pharmacy and the therapeutical use of drugs. By their relations with the further East, the Arabs became acquainted with valuable new remedies which have held their ground till modern times; and their skill in chemistry enabled them to prepare new chemical remedies, and form many combinations of those already in use. They produced the first pharmacopœia, and established the first apothecaries' shops. Many of the names and many forms of medicines now used, and in fact the general outline of modern pharmacy, except so far as modified by modern chemistry, started with the Arabs. Thus does Arabian medicine appear as judged from a modern standpoint; but to mediæval Europe, when little but a tradition remained of the great ancient schools, it was invested with a far higher degree of originality and importance.

It is now necessary to consider what was the state of medicine in Europe after the fall of the Western empire and before the influence of Arabian science and literature began to be felt. This we may call the pre-Arabian or Salernitan period.

*Medicine in the Early Middle Ages: School of Salerno.*—In medical as in civil history there is no real break. A continuous thread of learning and practice must have connected the last period of Roman medicine already mentioned with the dawn of science in the Middle Ages. But the intellectual thread is naturally traced with greater difficulty than that which is the theme of civil history; and in periods such as that from the 5th to the 10th century in Europe it is almost lost. The chief homes of medical as of other learning in these disturbed times were the monasteries. Though the science was certainly not advanced by their labours, it was saved from total oblivion, and many ancient medical works were preserved either in Latin or vernacular versions. The "Anglo-Saxon Leechdoms" of the 11th century, published in the Master of the Rolls series of mediæval chronicles and memorials, admirably illustrate the mixture of magic and superstition with the relics of ancient science which constituted monastic medicine. Similar works, in Latin or other languages, exist in manuscript in all the great European libraries. It was among the Benedictines that the monastic study of medicine first received a new direction, and aimed at a higher standard. The study of Hippocrates, Galen, and other classics was recommended by Cassiodorus (6th century), and in the original mother-abbey of Monte Cassino medicine was studied; but there was not there what could be called a medical school; nor had this foundation any connexion (as has been supposed) with the famous school of Salerno.

The origin of this, the most important source of medical knowledge in Europe in the early Middle Ages, is involved in obscurity. It is known that Salerno, a Roman colony, in a situation noted in ancient times for its salubrity, was in the 6th century at least the seat of a bishopric, and at the end of the 7th century of a Benedictine monastery, and that some of the prelates and higher clergy were distinguished for learning, and even for medical acquirements. But it has by recent researches been clearly established that the celebrated *Schola Salernitana* was a purely secular institution. All that can with certainty be said is that a school or collection of schools gradually grew up in which especially medicine, but also, in a subordinate degree, law and philosophy were taught. In the 9th century Salernitan physicians were already spoken of, and the city was known as *Civitas Hippocratica*. A little later we find great and royal personages resorting to Salerno for the restoration of their health, among whom was William of Normandy, afterwards the Conqueror. The number of students of medicine must at one time have been considerable, and in a corresponding degree the number of teachers. Among the latter many were married, and their wives and daughters appear also in the lists of professors. The most noted female professor was the celebrated Trotula in the 11th century. The Jewish element appears to have been important among the students, and possibly among the professors. The reputation of the school was great till the 12th or 13th century, when the introduction of the Arab medicine was gradually fatal to it. The foundation of the university of Naples, and the rise of Montpellier, also contributed to its decline.

The teachings of the Salernitan doctors are pretty well known through existing works, some of which have only recently been discovered and published. The best-known is the anonymous rhyming Latin poem on health, *Regimen Sanitatis Salerni*, professedly written for the use of the "king of England," supposed to mean Robert, son of William the Conqueror; it had an immense reputation in the Middle Ages, and was afterwards many times printed, and translated into most European languages. This was a popular work intended for the laity; but there are others strictly professional. Among the writers it may be sufficient to mention here Gariopontus; Copho, who wrote the *Anatome Porci*, a well-known mediæval book; Joannes Platearius, first of a family of physicians bearing the same name, whose *Practica*, or medical compendium, was afterwards several times printed; and Trotula, believed to be the wife of the last-named. All of these fall into the first period before the advent of Arabian medicine. In the transitional period, when the Arabian school began to influence European medicine, but before the Salernitans were superseded, comes Nicolaus Præpositus, who wrote the *Antidotarium*, a collection of formulæ for compound medicines, which became the standard work on the subject, and the foundation of many later compilations. An equally popular writer was Gilles de Corbeil (Ægidius Corboliensis), at one time a teacher at Salerno, afterwards court physician to Philip Augustus of France, who composed several poems in Latin hexameters on medical subjects. Two of them, on the urine and the pulse respectively, attained the position of medical classics.

None of these Salernitan works rise much above the rank of compilations, being founded on Hippocrates, Galen, and later Greek writers, with an unmistakable mixture of the doctrines of the methodists. But they often show much practical experience, and exhibit the naturalistic method of the Hippocratic school. The general plan of

treatment is dietetic rather than pharmaceutical, though the art of preparing drugs had reached a high degree of complexity at Salerno. Anatomy was as little regarded as it was in the later ancient schools, the empiric and methodic, but demonstrations of the parts of the body were given on swine. Although it cannot be said that the science of medicine was advanced at Salerno, still its decline was arrested at a time when every other branch of learning was rapidly falling into decay; and there can be no doubt that the observation of patients in hospitals, and probably clinical instruction, were made use of in learning and teaching. The school of Salerno thus forms a bridge between the ancient and the modern medicine, more direct though less conspicuous than that circuitous route, through Byzantium, Baghdad, and Cordova, by which Hippocrates and Galen, in Arabian dress, again entered the European world. Though the glory of Salerno had departed, the school actually existed till it was finally dissolved by an edict of the emperor Napoleon I. in the year 1811.

*Introduction of Arabian Medicine: The Scholastic Period.* — About the middle of the 11th century the Arabian medical writers began to be known by Latin translations in the Western world. Constantinus Africanus, a monk, was the author of the earliest of such versions (1050 A.D.); his labours were directed chiefly to the less important and less bulky Arabian authors, of whom Haly was the most noted; the real classics were not introduced till later. For some time the Salernitan medicine held its ground, and it was not till the conquest of Toledo by Alphonso of Castile that any large number of Western scholars came in contact with the learning of the Spanish Moors, and systematic efforts were made to translate their philosophical and medical works. Jewish scholars, often under the patronage of Christian bishops, were especially active in the work. In Sicily also the Oriental tendencies of Frederick Barbarossa and Frederick II. worked in the same direction. Gerard of Cremona, a physician of Toledo (1114–87), made translations, it is said by command of Barbarossa, from Avicenna and others. It is needless to point out the influence of the crusades in making Eastern ideas known in the Western world. The influence of Arabian medicine soon began to be felt even in the Hippocratic city of Salerno, and in the 13th century is said to have held an even balance with the older medicine. After this time the foreign influence predominated; and by the time that the Aristotelian dialectic, in the introduction of which the Arabs had so large a share, prevailed in the schools of Europe, the Arabian version of Greek medicine reigned supreme in the medical world. That this movement coincided with the establishment of some of the older European universities is well known. The history of medicine in the period now opening is closely combined with the history of scholastic philosophy. Both were infected with the same dialectical subtlety, which was, from the nature of the subject, especially injurious to medicine.

At the same time, through the rise of the universities, medical learning was much more widely diffused, and the first definite forward movement was seen in the school of Montpellier, where a medical faculty existed early in the 12th century, afterwards united with faculties of law and philosophy. The medical school owed its foundation largely to Jewish teachers, themselves educated in the Moorish schools of Spain, and imbued with the intellectual independence of the Averroists. Its rising prosperity coincided with the decline of the school of Salerno. Montpellier became distinguished for the practical and empirical spirit of its medicine, as contrasted with the dogmatic and scholastic teaching of Paris and other universities. In Italy, Bologna and Padua were earliest distinguished for medical studies,—the former preserving more of the Galenical tradition, the latter being more progressive and Averroist. The northern universities contributed little,—the reputation even of Paris being of later growth.

The supremacy of Arabian medicine lasted till the revival of learning, when the study of the medical classics in their original language worked another revolution. The medical writers of this period, who chiefly drew from Arabian sources, have been called Arabists (though it is difficult to give any clear meaning to this term), and were afterwards known as the neoterics.

The medical literature of this period is extremely voluminous, but essentially second-hand, consisting mainly of commentaries on Hippocrates, Galen, Avicenna, and others, or of compilations and *compendia* still less original than commentaries. Among these may be mentioned the *Conciliator* of Peter of Abano (1250–1315), the *Aggregator* of Jacob de Dondi (1298–1359), both of the school of Padua, and the *Pandectæ Medicinæ* of the Salernitan Matthæus Sylvaticus (*ob.* 1342), a sort of medical glossary and dictionary. But for us the most interesting fact is the first appearance of Englishmen as authors of medical works having a European reputation, distinguished, according to the testimony of Haeser, by a practical tendency characteristic of the British race, and fostered in the school of Montpellier.

The first of these works is the *Compendium Medicinæ*, also called *Laurea* or *Rosa Anglicana*, of Gilbert (Gilbertus Anglicus, about 1290), said to contain good observations on leprosy. A more important work, the *Practica seu Lilium Medicinæ*, of Bernard Gordon, a Scottish professor at Montpellier (written in the year 1307), was more widely spread, being translated into French and Hebrew, and printed in several editions. Of these two physicians the first probably, the latter certainly, was educated and practised abroad, but John Gaddesden, the author of *Rosa Anglica seu Practica Medicinæ* (between 1305 and 1317), was a graduate in medicine of Merton College, Oxford, and court physician. His compendium is entirely wanting in originality, and perhaps unusually destitute of common sense, but it became so popular as to be reprinted up to the end of the 16th century. Works of this kind became still more abundant in the 14th and in the first half of the 15th century, till the wider distribution of the medical classics in the original put them out of fashion.

In surgery this period was far more productive than in medicine, especially in Italy and France, but the limits of our subject only permit us to mention Gulielmus de Saliceto of Piacenza (about 1275), Lanfranchi of Milan (died about 1306), the French surgeon, Guy de Chauliac (about 1350), and the Englishman, John Ardern (about 1350). In anatomy also the beginning of a new epoch was made by Mondino de Liucci, or Mundinus (1275–1326), and his followers. Some advance was made in chemistry by the celebrated Arnold de Villanova (1235–1312), whose medical writings (if the *Breviarium Practicæ* be rightly ascribed to him) rise above the rank of compilations. Finally, in the 13th and especially the 14th century, we find, under the name of *consilia*, the first mediæval reports of medical cases which are preserved in such a form as to be intelligible. Collections of *consilia* were published, among others, by Gentilis Fulgineus before 1348, by Bartolomeo Montagnana (died in 1470), and by Baverius de Baveriis of Imola (about 1450). The last-named, we can say from experience, contains much that is interesting and readable.

*Period of the Revival of Learning.*—The impulse which all departments of intellectual activity received from the revival of Greek literature in Europe was felt by medicine among the rest. Not that the spirit of the science, or of its corresponding practice, was at once changed. The

basis of medicine through the Middle Ages had been literary and dogmatic, and it was literary and dogmatic still; but the medical literature now brought to light, including as it did the more important works of Hippocrates and Galen, many of them hitherto unknown, and in addition the forgotten element of Latin medicine, especially the work of Celsus, was in itself far superior to the second-hand compilations and incorrect versions which had formerly been accepted as standards. The classical works, though still regarded with unreasoning reverence, were found to have a germinative and vivifying power that carried the mind out of the region of dogma, and prepared the way for the scientific movement which has been growing in strength up to our own day.

Two of the most important results of the revival of learning were indeed such as are excluded from the scope of this brief sketch, namely, the reawakening of anatomy, which to a large extent grew out of the study of the works of Galen, and the investigation of medicinal plants, to which a fresh impulse was given by the revival of Dioscorides and other ancient naturalists. The former brought with it necessarily a more accurate conception of physiology, and thus led up to the great discovery of Harvey, which was the turning-point in modern medicine. The latter gave rise, on the one hand, to the modern science of botany, on the other to a more rational knowledge of drugs and their uses. At the same time, the discovery of America, and increased intercourse with the East, by introducing a variety of new plants, greatly accelerated the progress both of botany and pharmacology.

But it was not in these directions that improvement was first looked for. It was at first very naturally imagined that the simple revival of classical and especially of Greek literature would at once produce the same brilliant results in medicine as in literature and philosophy. The movement of reform started, of necessity, with scholars rather than practising physicians,—more precisely with a group of learned men, whom we may be permitted, for the sake of a name, to call the medical humanists, equally enthusiastic in the cause of letters and of medicine. From both fields they hoped to expel the evils which were summed up in the word barbarism. Nearly all mediæval medical literature was condemned under this name; and for it the humanists proposed to substitute the originals of Hippocrates and Galen, thus leading back medicine to its fountain-head. Since a knowledge of Greek was still confined to a small body of scholars, and a still smaller proportion of physicians, the first task was to translate the Greek classics into Latin. To this work several learned physicians, chiefly Italians, applied themselves with great ardour. Among the earliest were Nicolaus Leonicenus of Vicenza (1428–1524), Giovanni de Monte or Montanus (1498–1552), and many others in Italy. In northern Europe should be mentioned Gulielmus Copus (1471–1532) and Günther of Andernach (1487–1584) better known as Guinterius Andernacensis, both for a time professors at Paris; and, among the greatest, Thomas Linacre (about 1460–1524; see LINACRE). A little later Janus Cornarius or Hagenbut (1500–58) and Leonard Fuchs (1501–66) in Germany, and John Kaye or Caius (1510–72) in England, carried on the work. Symphorien Champier (Champerius or Campegius) of Lyons (1472–1539), a contemporary of Rabelais, and the patron of Servetus, wrote with fantastic enthusiasm on the superiority of the Greek to the Arabian physicians, and possibly did something to enlist in the same cause the two far greater men just mentioned. Rabelais not only lectured on Galen and Hippocrates, but edited some works of the latter; and Servetus, in a little tract *Syruporum universa ratio*, defended the practice of Galen as compared with that of the Arabians. The great Aldine press made an important contribution to the work, by *editiones principes* of Hippocrates and Galen in the original. Thus was the campaign opened against the mediæval and Arabian writers, till finally Greek medicine assumed a predominant position, and Galen took the place of Avicenna. The result was recorded in a formal manner by the Florentine Academy, sometime shortly before 1535: "quæ, excusso Arabicæ et barbaræ servitutis medicæ jugo, ex professo se Galenicam appellavit et profligato barbarorum exercitu unum totum et solum Galenum, ut optimum artis medicæ authorem, in omnibus se sequuturam pollicita est." Janus Cornarius, from whom this is quoted, laments, however, that the Arabians still reigned in most of the schools of medicine, and that the Italian and French authors of works called *Practica* were still in high repute. The triumph of Galenism was therefore not complete by the middle of the 16th century. It was probably most so, and earliest, in the schools of Italy and in those of England, where the London College of Physicians might be regarded as an offshoot of the Italian schools. Paris was the stronghold of conservatism, and Germany was stirred by the teachings of one who must be considered apart from all schools—Paracelsus. The nature of the struggle between the rival systems may be well illustrated by a formidable controversy about the rules for bleeding in acute diseases. This operation, according to the Arabian practice, was always performed on a vein at a distance from the organ affected. The Hippocratic and also Galenic rule, to let blood from, or near to, the diseased organ, was revived by Brissot (1470–1522), a professor in the university of Paris. His attempt at reform, which was taken to be, as in effect it was, a revolt against the authority of the Arabian masters, led to his expulsion from Paris, and the formal prohibition by the parliament of his method. Upon this apparently trifling question arose a controversy which lasted many years, occupied several universities, and led to the interposition of personages no less important than the pope and the emperor, but which is thought to have largely contributed to the final downfall of the Arabian medicine.

*Paracelsus and Chemical Medicine.*—Contemporary with the school of medical humanists, but little influenced by them, lived in Germany a man of strange genius, of whose character and importance the most opposite opinions have been expressed. The first noticeable quality in Paracelsus (*c.* 1490–1541) is his revolutionary independence of thought, which was supported by his immense personal arrogance. Himself well trained in the learning and medical science of the day, he despised and trampled upon all traditional and authoritative teachings. He began his lectures at Basel by burning the books of Avicenna and others; he afterwards boasted of having read no books for ten years; he protested that his shoe buckles were more learned than Galen and Avicenna. On the other hand, he spoke with respect of Hippocrates, and wrote a commentary on his *Aphorisms*. In this we see a spirit very different from the enthusiasm of the humanists for a purer and nobler philosophy than the scholastic and Arabian versions of Greek thought. There is no record of Paracelsus's knowledge of Greek, and as, at least in his student days, the most important works of Greek medicine were very imperfectly known, it is probable he had little first-hand acquaintance with Galen or Hippocrates, while his breach with the humanists is the more conspicuous from his lecturing and writing chiefly in his native German.

Having thus made a clean sweep of nearly the whole of the dogmatic medicine, what did Paracelsus put in its place? Certainly not pure empiricism, or habits of objective observation. He had a dogma of his own,—one founded, according to his German expositors, on the views of the

Neo-Platonists, of which a few disjointed specimens must here suffice. The human body was a "microcosm" which corresponded to the "macrocosm," and contained in itself all parts of visible nature,—sun, moon, stars, and the poles of heaven. To know the nature of man and how to deal with it, the physician should study, not anatomy, which Paracelsus utterly rejected, but all parts of external nature. Life was a perpetual germinative process controlled by the indwelling spirit or Archeus; and diseases, according to the mystical conception of Paracelsus, were not natural, but spiritual. Nature was sufficient for the cure of most diseases; art had only to interfere when the internal physician, the man himself, was tired or incapable. Then some remedy had to be introduced which should be antagonistic, not to the disease in a physical sense, but to the spiritual seed of the disease. These remedies were *arcana*, —a word corresponding partly to what we now call specific remedies, but implying a mysterious connexion between the remedy and the "essence" of the disease. Arcana were often shown to be such by their physical properties, not only by such as heat, cold, &c., but by fortuitous resemblances to certain parts of the body; thus arose the famous doctrine of "signatures," or signs indicating the virtues and uses of natural objects, which was afterwards developed into great complexity. Great importance was also attached to chemically prepared remedies as containing the essence or spiritual quality of the material from which they were derived. The actual therapeutical resources of Paracelsus included a large number of metallic preparations, in the introduction of some of which he did good service, and, among vegetable preparations, the tincture of opium, still known by the name he gave it, laudanum. In this doubtless he derived much advantage from his knowledge of chemistry, though the science was as yet not disentangled from the secret traditions of alchemy, and was often mixed up with imposture.

German historians of medicine attach great importance to the revolt of Paracelsus against the prevailing systems, and trace in his writings anticipations of many scientific truths of later times. That his personality was influential, and his intrepid originality of great value as an example in his own country, is undeniable. As a national reformer he has been not inaptly compared to Luther. But his importance in the universal history of medicine we cannot estimate so highly. The chief immediate result we can trace is the introduction of certain mineral remedies, especially antimony, the use of which became a kind of badge of the disciples of Paracelsus. The use of these remedies was not, however, necessarily connected with a belief in his system, which seems to have spread little beyond his own country. Of the followers of Paracelsus some became mere mystical quacks and impostors. Others, of more learning and better repute, were distinguished from the regular physicians chiefly by their use of chemical remedies. In France the introduction of antimony gave rise to a bitter controversy which lasted into the 17th century, and led to the expulsion of some men of mark from the Paris faculty. In England "chemical medicine" is first heard of in the reign of Elizabeth, and was in like manner contemned and assailed by the College of Physicians and the Society of Apothecaries. But it should be remembered that all the chemical physicians did not call Paracelsus master. The most notorious of that school in England, a certain Anthony, never quotes Paracelsus, but relies upon Arnold de Villanova and Raymund Lully. From this time, however, it is always possible to trace a school of chemical practitioners, who, though condemned by the orthodox Galenists, held their ground, till in the 17th century a successor of Paracelsus arose in the celebrated Van Helmont.

*Consequences of the Revival of Ancient Medicine.*—The revival of Galenic and Hippocratic medicine, though ultimately it conferred the greatest benefits on medical science, did not immediately produce any important or salutary reform in practical medicine. The standard of excellence in the ancient writers was indeed far above the level of the 16th century; but the fatal habit of taking at second hand what should have been acquired by direct observation retarded progress more than the possession of better models assisted it, so that the fundamental faults of mediæval science remained uncorrected.

Nevertheless some progress has to be recorded, even if not due directly to the study of ancient medicine. In the first place the 15th and 16th centuries were notable for the outbreak of certain epidemic diseases, which were unknown to the old physicians. Of these the chief was the "sweating sickness" or "English sweat," especially prevalent in, though not confined to, the country whence it is named. Among many descriptions of this disease, that by John Kaye or Caius, already referred to, was one of the best, and of great importance as showing that the works of Galen did not comprise all that could be known in medicine. The spread of syphilis, a disease equally unknown to the ancients, and the failure of Galen's remedies to cure it, had a similar effect.

In another direction the foundations of modern medicine were being laid during the 16th century, namely, by the introduction of clinical instruction in hospitals. In this Italy, and especially the renowned school of Padua, took the first step, where De Monte (Montanus), already mentioned as a humanist, gave clinical lectures on the patients in the hospital of St Francis, which may still be read with interest. Pupils flocked to him from all European countries; Germans are especially mentioned; a Polish student reported and published some of his lectures; and the Englishman Kaye was a zealous disciple, who does not, however, seem to have done anything towards transplanting this method of instruction to his own country. Inspections of the dead, to ascertain the nature of the disease, were made, though not without difficulty, and thus the modern period of the science of morbid anatomy was ushered in.

*Medicine in the 17th century.*—The medicine of the early part of the 17th presents no features to distinguish it from that of the preceding century. The practice and theory of medicine were mainly founded upon Hippocrates and Galen, with ever-increasing additions from the chemical school. But the development of mathematical and physical science soon introduced a fundamental change in the habits of thought with respect to medical doctrine.

These discoveries not only weakened or destroyed the respect for authority in matters of science, but brought about a marked tendency to mechanical explanations of life and disease. When Harvey by his discovery of the circulation furnished an explanation of many vital processes which was reconcileable with the ordinary laws of mechanics, the efforts of medical theorists were naturally directed to bringing all the departments of medicine under similar laws. It is often assumed that the writings and influence of Bacon did much towards introducing a more scientific method into medicine and physiology. But, without discussing the general philosophical position or historical importance of Bacon, it may safely be said that his direct influence can be little traced in medical writings of the first half of the 17th century. Harvey, as is well known, spoke slightingly of the great chancellor, and it is not till the rapid development of physical science in England and Holland in the latter part of the century, that we find Baconian principles explicitly recognized.

The dominant factors in the 17th century medicine were

the discovery of the circulation by Harvey (published in 1628), the mechanical philosophy of Descartes and the contemporary progress of physics, the teaching of Van Helmont and the introduction of chemical explanations of morbid processes, and finally, combined of all these, and inspiring them, the rise of the spirit of inquiry and innovation, which may be called the scientific movement. Before speaking in detail of these, we may note that by other influences, quite independent of theories, important additions were made to practical medicine. The method of clinical instruction in hospitals, commenced by the Italians, was introduced into Holland, where it was greatly developed, especially at Leyden, in the hands of the celebrated Sylvius. It is noteworthy that concurrently with the rise of clinical study the works of Hippocrates were more and more valued, while Galen began to sink into the background.

At the same time the discovery of new diseases, unknown to the ancients, and the keener attention which the great epidemics of plague caused to be paid to those already known, led to more minute study of the natural history of disease. The most important disease hitherto undescribed was rickets, first made known by Arnold de Boot, a Frisian who practised in Ireland, in 1649, and afterwards more fully in the celebrated work of Glisson in 1651. The plague was carefully studied by Diemerbroek (*De Peste*, 1646) and others. Hodges, of London, in 1665 seems to have been the first who had the courage to make a post-mortem inspection of a plague patient. Bennet wrote an important work on consumption in 1654. During the same period many new remedies were introduced, the most important being cinchona bark, brought to Spain in the year 1640. The progress of pharmacy was shown by the publication of *Dispensatories* or *Pharmacopœiæ*, such as that of the Royal College of Physicians of London in 1618. This, like the earlier German works of the same kind (on which it was partly founded), contains both the traditional (Galenical) and the modern or chemical remedies.

*Van Helmont.*—The medicine of the 17th century was especially distinguished by the rise of systems; and we must first speak of an eccentric genius who endeavoured to construct a system for himself, as original and opposed to tradition as that of Paracelsus. Van Helmont (1578–1644) was a man of noble family in Brussels, who, after mastering all other branches of learning as then understood, devoted himself with enthusiasm to medicine and chemistry. By education and position a little out of the regular lines of the profession, he took up in medicine an independent attitude. Well acquainted with the doctrines of Galen, he rejected them as thoroughly as Paracelsus did, and borrowed from the latter some definite ideas as well as his revolutionary spirit. The archeus of Paracelsus appears again, but with still further complications,—the whole body being controlled by the *archeus influus*, and the organ of the soul and its various parts by the *archei insiti*, which are subject to the central archeus. Many of the symptoms of diseases were caused by the passions and perturbations of the archeus, and medicines acted by modifying the *ideas* of the same archeus. These and other notions cannot be here stated at sufficient length to be intelligible. It is enough to say that on this fantastic basis Helmont constructed a medical system which had some practical merits, that his therapeutical methods were mild and in many respects happy, and that he did service by applying newer chemical methods to the preparation of drugs. He thus had some share, though a share not generally recognized, in the foundation of the iatro-chemical school, now to be spoken of. But his avowed followers formed a small and discredited sect, which, in England at least, can be clearly traced in the latter part of the century.

*Discovery of the Circulation of the Blood.*—The influence of Harvey's discovery began to be felt before the middle of the century. Its merits were recognized by Descartes, among the first, nine years after its publication. For the history of the discovery, and its consequences in anatomy and physiology, we must refer to the article HARVEY. In respect of practical medicine, much less effect was at first noticeable. But this example, combined with the Cartesian principles, set many active and ingenious spirits to work to reconstruct the whole of medicine on a physiological or even a mechanical basis,—to endeavour to form what we should now call physiological or scientific medicine. The result of this was not to eliminate dogma from medicine, though it weakened the authority of the old dogma. The movement led rather to the formation of schools or systems of thought, which under various names lasted on into the 18th century, while the belief in the utility or necessity of schools and systems lasted much longer. The most important of these were the so-called iatro-physical or mechanical and the iatro-chemical schools.

*Iatro-Physical School.*—The iatro-physical school of medicine grew out of physiological theories. Its founder is held to have been Borelli of Naples (1608–79), whose treatise *De motu animalium*, published in 1680, is regarded as marking an epoch in physiology. The tendency of the school was to explain the actions and functions of the body on physical and especially on mechanical principles. The movements of bones and muscles were referred to the theory of levers; the process of digestion was regarded as essentially a process of trituration; nutrition and secretion were shown to be dependent upon the tension of the vessels, and so forth. The developments of this school belong rather to the history of physiology, where they appear, seen in the light of modern science, as excellent though premature endeavours in a scientific direction. But the influence of these theories on practical medicine was not great. The more judicious of the mechanical or physical school refrained, as a judicious modern physiologist does, from too immediate an application of their principles to daily practice. Mechanical theories were introduced into pathology, in explanation of the processes of fever and the like, but had little or no influence on therapeutics. The most important men in this school after Borelli were Steno (1638–86), Baglivi (1673–1707), and Bellini (1643–1704). An English physician, Cole (1660–1700), is also usually ranked with them. One of the most elaborate developments of the system was that of Pitcairn, a Scottish physician who became professor at Leyden (1652–1713), to be spoken of hereafter.

*Iatro-Chemical School.*—The so-called iatro-chemical school stood in a much closer relation to practical medicine than the iatro-physical. The principle which mainly distinguished it was not merely the use of chemical medicines in addition to the traditional, or, as they were called in distinction, "Galenical" remedies, but a theory of pathology or causation of disease entirely different from the prevailing "humoral" pathology. Its chief aim was to reconcile the new views in physiology and chemistry with practical medicine. In some theoretical views, and in the use of certain remedies, the school owed something to Van Helmont and Paracelsus, but took in the main an independent position. The founder of the iatro-chemical school was Francis de le Boë, called Sylvius (1614–72), belonging to a French family settled in Holland. Sylvius was for fourteen years professor of medicine at Leyden, where he attracted students from all quarters of Europe. He made a resolute attempt to reconstruct medicine on the two bases of the doctrine of the circulation of the blood and the new views of chemistry. Fermentation, which was supposed to take place in the stomach, played an important

part in the vital processes. Chemical disturbances of these processes, called *acridities*, &c., were the cause of fevers and other diseases. Sometimes acid sometimes alkaline properties predominated in the juices and secretions of the body, and produced corresponding disturbances. In nervous diseases disturbances of the vital "spirits" were most important. Still in some parts of his system Sylvius shows an anxiety to base his pathology on anatomical changes. The remedies he employed were partly Galenical, partly chemical. He was very moderate in the use of bleeding.

The doctrines of Sylvius became widely spread in Holland and Germany; less so in France and Italy. In England they were not generally accepted, till adopted with some modifications by Thomas Willis the great anatomist (1622–75), who is the chief English representative of the chemical school. Willis was as thorough-going a chemist as Sylvius. He regarded all bodies, organic and inorganic, as composed of the three elements—spirit, sulphur, and salt, the first being only found abundantly in animal bodies. The "intestine movement of particles" in every body, or fermentation, was the explanation of many of the processes of life and disease. The sensible properties and physical alterations of animal fluids and solids depended upon different proportions, movements, and combinations of these particles. The elaborate work *Pharmaceutice Rationalis*, based on these materials, had much influence in its time, though it was soon forgotten. But some parts of Willis's works, such as his descriptions of nervous diseases, and his account (the earliest) of diabetes, are classical contributions to scientific medicine. In the application of chemistry to the examination of secretions Willis made some important steps. The chemical school met with violent opposition, partly from the adherents of the ancient medicine, partly from the iatro-mechanical school. Towards the end of the 17th century appeared an English medical reformer who sided with none of these schools, but may be said in some respects to have surpassed and dispensed with them.

*Sydenham and Locke.*—Thomas Sydenham (1624–89) was educated at Oxford and at Montpellier. He was well acquainted with the works of the ancient physicians, and probably fairly so with chemistry. Of his knowledge of anatomy nothing definite can be said, as he seldom refers to it. His main avowed principle was to do without hypothesis, and study the actual diseases in an unbiassed manner. As his model in medical methods, Sydenham repeatedly and pointedly refers to Hippocrates, and he has not unfairly been called the English Hippocrates. He resembled his Greek master in the high value he set on the study of the "natural history of disease"; in the importance he attached to "epidemic constitution," that is, to the influence of weather and other natural causes in modifying disease; and further in his conception of the healing power of nature in disease, a doctrine which he even expanded beyond the teaching of Hippocrates. According to Sydenham, a disease is nothing more than an effort of nature to restore the health of the patient by the elimination of the morbific matter. The extent to which his practice was influenced by this and other *a priori* conceptions prevents us from classing Sydenham as a pure empiric, but he had the rare merit of never permitting himself to be enslaved even by his own theories. Still less was his mind warped by either of the two great systems, the classical and the chemical, which then divided the medical world. Sydenham's influence on European medicine was very great. His principles were welcomed as a return to nature by those who were weary of theoretical disputes. He introduced a milder and better way of treating fevers, especially small-pox, and gave strong support to the use of specific medicines, especially Peruvian bark. He was an advocate of bleeding, and often carried it to excess. Another important point in Sydenham's doctrine is his clear recognition of many diseases as being what would be now called *specific*, and not due merely to an alteration in the primary qualities or humours of the older schools. From this springs his high appreciation of specific medicines.

One name should always be mentioned along with Sydenham—that of his friend John Locke. The great sensational philosopher was a thoroughly trained physician, and practised privately. He shared and defended many of Sydenham's principles, and in the few medical observations he has left shows himself to be even more thorough-going than the "English Hippocrates." It is deeply to be regretted in the interests of medicine that he did not write more. It is, however, reasonable to suppose that his commanding intellect often makes itself felt in the words of Sydenham. One sentence of Locke's in a letter to W. Molyneux sums up the practical side of Sydenham's teaching.

"You cannot imagine how far a little observation carefully made by a man not tied up to the four humours [Galen], or sal, sulphur, and mercury [Paracelsus], or to acid and alcali [Sylvius and Willis] which has of late prevailed, will carry a man in the curing of diseases though very stubborn and dangerous; and that with very little and common things, and almost no medicine at all."

We thus see that, while the great anatomists, physicists, and chemists, men of the type of Willis, Borelli, and Boyle, were laying foundations which were later on built up into the fabric of scientific medicine, little good was done by the premature application of their half-understood principles to practice. The reform of practical medicine was effected by men who aimed at, and partly succeeded in, rejecting all hypothesis and returning to the unbiassed study of natural processes, as shown in health and disease.

Sydenham showed that these processes might be profitably studied and dealt with without explaining them; and, by turning men's minds away from explanations and fixing them on facts, he enriched medicine with a *method* more fruitful than any discoveries in detail. From this time forth the reign of canonical authority in medicine was at an end, though the dogmatic spirit long survived.

*The 18th century.*—The medicine of the 18th century is notable, like that of the latter part of the 17th, for the striving after complete theoretical systems. The influence of the iatro-physical school was by no means exhausted; and in England, especially through the indirect influence of Newton's great astronomical generalizations, it took on a mathematical aspect, and is sometimes known as iatro-mathematical. This phase is most clearly developed in Pitcairn (1652–1713), who, though a determined opponent of metaphysical explanations, and of the chemical doctrines, gave to his own rude mechanical explanations of life and disease almost the dogmatic completeness of a theological system. His countryman and pupil, George Cheyne, who lived some years at Bath, published a new theory of fevers on the mechanical system, which had a great reputation. Their English contemporaries and successors, Freind, Cole, and Mead, leaned also to mechanical explanations, but with a distrust of systematic theoretical completeness, which was perhaps partly a national characteristic, partly the result of the teaching of Sydenham and Locke. Freind (1675–1728) in his *Emmenologia* gave a mechanical explanation of the phenomena of menstruation. He is also one of the most distinguished writers on the history of medicine. Cole (see above) published mechanical hypotheses concerning the causation of fevers which closely agree with those of the Italian iatro-mechanical school. More distinguished in his own day than any of these was Richard Mead (1673–1754), one of the most accomplished and socially successful physicians of modern times. Mead was the pupil of the equally popular and successful John Radcliffe

(1650–1714), who had acquired from Sydenham a contempt for book learning, and belonged to no school in medicine but the school of common sense. Radcliffe left, however, no work requiring mention in a history of medicine. Mead, a man of great learning and intellectual activity, was an ardent advocate of the mathematical doctrines. "It is very evident," he says, "that all other means of improving medicine have been found ineffectual, by the stand it was at for two thousand years, and that, since mathematicians have set themselves to the study of it, men already begin to talk so intelligibly and comprehensibly, even about abstruse matters, that it is to be hoped that mathematical learning will be the distinguishing mark of a physician and a quack." His *Mechanical Account of Poisons*, in the first edition (1702), gave an explanation of the effects of poisons, as acting only on the blood. Afterwards he modified his hypothesis, and referred the disturbances produced to the "nervous liquor," which he supposed to be a quantity of the "universal elastic matter" diffused through the universe, by which Newton explained the phenomena of light, *i.e.*, what was afterwards called the luminiferous ether. Mead's treatise on *The Power of the Sun and Moon over Human Bodies* (1704), equally inspired by Newton's discoveries, was a premature attempt to assign the influence of atmospheric pressure and other cosmical causes in producing disease. His works contain, however, many original experiments, and excellent practical observations. James Keill (1673–1719) applied Newtonian and mechanical principles to the explanation of bodily functions with still greater accuracy and completeness; but his researches have more importance for physiology than for practical medicine.

*Boerhaave.*—None of these men founded a school,—a result due in part to their intellectual character, in part to the absence in England of medical schools equivalent in position and importance to the universities of the Continent. An important academical position was, on the other hand, one of the reasons why a physician not very different in his way of thinking from the English physicians of the age of Queen Anne was able to take a far more predominant position in the medical world. Hermann Boerhaave (1668–1738) was emphatically a great teacher. He was for many years professor of medicine at Leyden, where he lectured five hours a day, and excelled in influence and reputation, not only his greatest forerunners, Montanus of Padua and Sylvius of Leyden, but probably every subsequent teacher. The hospital of Leyden, though with only twelve beds available for teaching, became the centre of medical influence in Europe. Many of the leading English physicians of the 18th century studied there; Van Swieten, a pupil of Boerhaave, transplanted the latter's method of teaching to Vienna, and founded the noted Vienna school of medicine. As the organizer, and almost the constructor, of the modern method of clinical instruction, the services of Boerhaave to the progress of medicine were immense, and can hardly be overrated. In his teaching, as in his practice, he avowedly followed the method of Hippocrates and Sydenham, both of whom he enthusiastically admired. In his medical doctrines he must be pronounced an eclectic, though taking his stand mainly on the iatro-mechanical school. The best known parts of Boerhaave's system are his doctrines of inflammation, obstruction, and "plethora." By the last-named especially he was long remembered. His object was to make all the anatomical and physiological acquisitions of his age, even microscopical anatomy, which he diligently studied, available for use in the practice of medicine. He thus differed from Sydenham, who took almost as little account of modern science as of ancient dogma. Boerhaave may be in some respects compared to Galen, but again differed from him in that he always abstained from attempting to reduce his knowledge to a uniform and coherent system. Boerhaave attached great importance to the study of the medical classics, but rather treated them historically than quoted them as canonical authorities. It almost follows from the nature of the case that the great task of Boerhaave's life, a synthesis of ancient and modern medicine, and the work in which this is chiefly contained, his celebrated *Institutions*, could not have any great permanent value. Nearly the same thing is true even of the *Aphorisms*, in which, following the example of Hippocrates, he endeavoured to sum up the results of his long experience.

*Hoffmann and Stahl.*—We have now to speak of two writers in whom the systematic tendency of the 18th century showed itself most completely.

Friedrich Hoffmann (1660–1742), like Boerhaave, owed his influence, and perhaps partly his intellectual characteristics, to his academical position. He was in 1693 appointed the first professor of medicine in the university of Halle, then just founded by the elector Frederick III. Here he became, as did his contemporary and rival Stahl, a popular and influential teacher, though their university had not the European importance of Leyden. Hoffmann's "system" was apparently intended to reconcile the opposing "spiritual" and "materialistic" views of nature, and is thought to have been much influenced by the philosophy of Leibnitz. His medical theories rest upon a complete theory of the universe. Life depended upon a universally diffused ether, which animals breathe in from the atmosphere, and which is contained in all parts of the body. It accumulates in the brain, and there generates the "nervous fluid" or *pneuma*,—a theory closely resembling that of Mead on the "nervous liquor," unless indeed Mead borrowed it from Hoffmann. On this system are explained all the phenomena of life and disease. Health depends on the maintenance of a proper "tone" in the body,—some diseases being produced by excess of tone, or "spasm"; others by "atony," or want of tone. But it is impossible here to follow its further developments. Independently of his system, which has long ceased to exert any influence, Hoffmann made some contributions to practical medicine; and his great knowledge of chemistry enabled him to investigate the subject of mineral waters. He was equally skilful in pharmacy, but lowered his position by the practice, which would be unpardonable in a modern physician, of trafficking in secret remedies. Some of these are even to this day sold for the benefit of the orphanage at Halle.

George Ernest Stahl (1660–1734) was for more than twenty years professor of medicine at Halle, and thus a colleague of Hoffmann, whom he resembled in constructing a complete theoretical system, though their systems had little or nothing in common. Stahl's chief aim was to oppose materialism. For mechanical conceptions he substituted the theory of "animism,"—attributing to the soul the functions of ordinary animal life in man, while the life of other creatures was left to mechanical laws. The symptoms of disease were explained as efforts of the soul to rid itself from morbid influences, the soul acting reasonably with respect to the end of self-preservation. The anima thus corresponds partly to the "nature" of Sydenham, while in other respects it resembles the archeus of Van Helmont. Animism in its completeness met with little acceptance during the lifetime of its author, but influenced some of the iatro-physical school. Stahl was the author of the theory of "phlogiston" in chemistry, which in its day had great importance.

*Haller and Morgagni.*—From the subtleties of rival systems it is a satisfaction to turn to two movements in the medicine of the 18th century which, though they did not extinguish the spirit of system-making, opened up paths of

investigation by which the systems were ultimately superseded. These are physiology in the modern sense, as dating from Haller, and pathological anatomy, as dating from Morgagni.

Albrecht von Haller (1708–77) was a man of even more encyclopædic attainments than Boerhaave. He advanced chemistry, botany, anatomy, as well as physiology, and was incessantly occupied in endeavouring to apply his scientific studies to practical medicine, thus continuing the work of his great teacher Boerhaave. Besides all this he was probably more profoundly acquainted with the literature and bibliography of medicine than any one before or since. Haller occupied in the new university of Göttingen (founded 1737) a position corresponding to that of Boerhaave at Leyden, and in like manner influenced a very large circle of pupils. The appreciation of his work in physiology belongs to the history of that science; we are only concerned here with its influence on medicine. Haller's definition of irritability as a property of muscular tissue, and its distinction from sensibility as a property of nerves, struck at the root of the prevailing hypothesis respecting animal activity. It was no longer necessary to suppose that a half conscious "anima" was directing every movement. Moreover, Haller's views did not rest on *a priori* speculation, but on numerous experiments. He was among the first to investigate the action of medicines on healthy persons. Unfortunately the lesson which his contemporaries learnt was not the importance of experiment, but only the need of contriving other "systems" less open to objection; and thus the influence of Haller led directly to the theoretical subtleties of Cullen and John Brown, and only indirectly and later on to the general anatomy of Bichat. The great name of Haller does not therefore occupy a very prominent place in the history of practical medicine.

The work of Giovanni Battista Morgagni (1682–1771) had and still preserves a permanent importance beyond that of all the contemporary theorists. In a series of letters *De sedibus et causis morborum per anatomen indagatis*, published when he was in his eightieth year, he describes the appearances met with at the post-mortem examination as well as the symptoms during life in a number of cases of various diseases. It was not the first work of the kind. Bonet had published his *Sepulcretum* in 1679; and observations of post-mortem appearances had been made by Montanus, Tulp, Vieussens, Valsalva, Lancisi, Haller, and others. But never before was so large a collection of cases brought together, described with such accuracy, or illustrated with equal anatomical and medical knowledge. Morgagni's work at once made an epoch in the science. Morbid anatomy now became a recognized branch of medical research, and the movement was started which has lasted till our own day.

The contribution of Morgagni to medical science must be regarded as in some respects the counterpart of Sydenham's. The latter had, in neglecting anatomy, neglected the most solid basis for studying the natural history of disease; though perhaps it was less from choice than because his practice, as he was not attached to a hospital, gave him no opportunities. But it is on the combination of the two methods, that of Sydenham and of Morgagni, that modern medicine rests; and it is through these that it has been able to make steady progress in its own field, independently of the advance of physiology or other sciences.

The method of Morgagni found many imitators, both in his own country and in others. In England the first important name in this field is at the same time that of the first writer of a systematic work in any language on morbid anatomy, Matthew Baillie (1761–1823), who published his treatise in 1793.

*Cullen and Brown.*—It remains to speak of two systematic writers on medicine in the 18th century, whose great reputation prevents them from being passed over, though their real contribution to the progress of medicine was not great—Cullen and Brown.

William Cullen (1712–90) was a most eminent and popular professor of medicine at Edinburgh. The same academical influences as surrounded the Dutch and German founders of systems were doubtless partly concerned in leading him to form the plan of a comprehensive system of medicine. Cullen's system was largely based on the new physiological doctrine of irritability, but is especially noticeable for the importance attached to nervous action. Thus even gout was regarded as a "neurosis." These pathological principles of Cullen are contained in his *First Lines of the Practice of Physic*, an extremely popular book, often reprinted and translated. More importance is to be attached to his *Nosology or Classification of Diseases*. The attempt to classify diseases on a natural-history plan was not new, having been commenced by Sauvages and others, and is perhaps not a task of the highest importance. Cullen drew out a classification of great and needless complexity, the chief part of which is now forgotten, but several of his main divisions are still preserved.

It is difficult to form a clear estimate of the importance of the last systematizer of medicine, John Brown (1735–88), for, though in England he has been but little regarded, the wide though short-lived popularity of his system on the Continent shows that it must have contained some elements of brilliancy, if not originality. His theory of medicine professed to explain the processes of life and disease, and the methods of cure, upon one simple principle,—that of the property of "excitability," in virtue of which the "exciting powers," defined as being (1) external forces and (2) the functions of the system itself, call forth the vital phenomena "sense, motion, mental function, and passion." All exciting powers are stimulant, the apparent debilitating or sedative effect of some being due to a deficiency in the degree of stimulus; so that the final conclusion is that "the whole phenomena of life, health as well as disease, consist in stimulus and nothing else." Brown recognized some diseases as *sthenic*, others as *asthenic*, the latter requiring stimulating treatment, the former the reverse; but his practical conclusion was that 97 per cent. of all diseases required a "stimulating" treatment. In this he claimed to have made the most salutary reform because all physicians from Hippocrates had treated diseases by depletion and debilitating measures with the object of curing by elimination. It would be unprofitable to attempt a complete analysis of the Brunonian system; and it is difficult now to understand why it attracted so much attention in its day. To us at the present time it seems merely a dialectical construction, having its beginning and end in definitions, the words power, stimulus, &c., being used in such a way as not to correspond to any precise physical conceptions, still less to definite material objects or forces. One recommendation of the system was that it favoured a milder system of treatment than was at that time in vogue; Brown may be said to have been the first advocate of the modern stimulant or feeding treatment of fevers. He advocated the use of "animal soups" or beef tea. Further he had the discernment to see that certain symptoms, such as convulsions and delirium, which were then commonly held always to indicate inflammation, were often really signs of weakness.

The fortunes of Brown's system (called, from having been originally written in Latin, the Brunonian) form one of the strangest chapters in the history of medicine. In Scotland, Brown so far won the sympathy of the students that riotous conflicts took place between his partisans and opponents. In England his system took little root. In Italy, on the other hand, it received enthusiastic support, and, naturally,

a corresponding degree of opposition. The most important adherent to Brown's system was Rasori (1763–1837), who taught it as professor at Pavia, but afterwards substituted his own system of contra-stimulus. The theoretical differences between this and the "stimulus" theory need not be expounded. The practical difference in the corresponding treatment was very great, as Rasori advocated a copious use of bleeding and of depressing remedies, such as antimony. Joseph Frank, a German, professor at Pavia, afterwards of Vienna, the author of an encyclopædic work on medicine now forgotten, embraced the Brunonian system, though he afterwards introduced some modifications, and transplanted it to Vienna. Many names are quoted as partisans or opponents of the Brunonian system in Italy, but scarcely one of them has any other claim to be remembered. In Germany the new system called forth, a little later, no less enthusiasm and controversial heat. Girtanner first began to spread the new ideas (though giving them out as his own), but Weikard was the first avowed advocate of the system. Röschlaub (1768–1835) modified Brown's system into the theory of excitement (*Erregungstheorie*), which for a time was extremely popular in Germany. The enthusiasm of the younger Brunonians in Germany was as great as in Edinburgh or in Italy, and led to serious riots in the university of Göttingen. In America the system was enthusiastically adopted by a noted physician, Benjamin Rush, of Philadelphia, who was followed by a considerable school. France was not more influenced by the new school than England. In both countries the tendency towards positive science and progress by objective investigation was too marked for any theoretical system to have more than a passing influence. In France, however, the influence of Brown's theories is very clearly seen in the writings of Broussais, who, though not rightly classed with the system-makers, since his conclusions were partly based upon anatomical investigation, resembled them in his attempt to unite theory and practice in one comprehensive synthesis. The explanation of the meteoric splendour of the Brunonian system in other countries seems to be as follows. In Italy the period of intellectual decadence had set in, and no serious scientific ardour remained to withstand the novelties of abstract theory. In Germany the case was somewhat different. Intellectual activity was not wanting, but the great achievements of the 18th century in philosophy and the moral sciences had fostered a love of abstract speculation; and some sort of cosmical or general system was thought indispensable in every department of special science. Hence another generation had to pass away before Germany found herself on the level, in scientific investigation, of France and England.

Before the theoretic tendency of the 18th century was quite exhausted, it displayed itself in a system which, though in some respects isolated in the history of medicine, stands nearest to that of Brown,—that, namely, of Hahnemann (see HOMŒOPATHY). Hahnemann (1753–1844) was in conception as revolutionary a reformer of medicine as Paracelsus. He professed to base medicine entirely on a knowledge of symptoms, regarding all investigation of the causes of symptoms as useless. While thus rejecting all the lessons of morbid anatomy and pathology, he put forward views respecting the causes of disease which hardly bear to be seriously stated. All chronic maladies result either from three diseases—psora (the itch), syphilis, or sycosis (a skin disease), or else are maladies produced by medicines. Seven-eighths of all chronic diseases are produced by itch driven inwards.[1] (It is fair to say that these views were published in one of his later works.) In treatment of disease Hahnemann rejected entirely the notion of a *vis medicatrix naturæ*, and was guided by his well-known principle "similia similibus curantur," which he explained as depending on the law that in order to get rid of a disease some remedy must be given which should substitute for the disease an action dynamically similar, but weaker. The original malady being thus got rid of, the vital force would easily be able to cope with and extinguish the slighter disturbance caused by the remedy. Something very similar was held by Brown, who taught that "indirect debility" was to be cured by a lesser degree of the same stimulus as had caused the original disturbance. Generally, however, Hahnemann's views contradict those of Brown, though moving somewhat in the same plane. In order to select remedies which should fulfil the indication of producing symptoms like those of the disease, Hahnemann made many observations of the action of drugs on healthy persons. He did not originate this line of research, for it had been pursued if not originated by Haller, and cultivated systematically by Tommasini, an Italian "contra-stimulist;" but he carried it out with much elaboration. His results, nevertheless, were vitiated by being obtained in the interest of a theory, and by singular want of discrimination. Hahnemann's doctrines met with much opposition on the part of the medical profession, and he was hence led to state his case to the "lay" public as a sort of court of appeal; and thus matters of science were made the theme of much popular controversy. This expedient, in which Hahnemann had been in a small degree anticipated by Brown, contributed largely to the success of his system. The appeal flattered a prevalent belief in the right of private judgement, even in technical and learned subjects. Hahnemann was thus able to take up the position (and not without justification) of a victim of professional prejudice. The anomalous position into which professional scorn and extra-professional popularity brought him produced a distinct deterioration in the character of his work. In his second period he developed the extraordinary theory of "potentiality" or dynamization,—namely, that medicines gained in strength by being diluted, if the dilution was accompanied by shaking or pounding, which was supposed to "potentialize" or increase the potency of the medicine. On this extraordinary principle Hahnemann ordered his original tinctures to be reduced in strength to one-fiftieth; these first dilutions again to one-fiftieth; and so on, even till the thirtieth dilution, which he himself used by preference, and to which he ascribed the highest "potentiality." It is hardly necessary to point out that even the lower dilutions involve quantities which no analysis can weigh, measure, or even recognize. The still greater eccentricities of Hahnemann's later works need not be recounted. From a theoretical point of view Hahnemann's is one of the abstract systems, pretending to universality, which modern medicine neither accepts nor finds it worth while to controvert. In the treatment of disease his practical innovations came at a fortunate time, when the excesses of the depletory system had only partially been superseded by the equally injurious opposite extreme of Brown's stimulant treatment. Hahnemann's use of mild and often quite inert remedies contrasted favourably with both of these. Further he did good by insisting upon simplicity in prescribing, when it was the custom to give a number of drugs, often heterogeneous and inconsistent, in the same prescription. But these indirect benefits were quite independent of the truth or falsity of his theoretical system.

*Positive Progress in the 18th Century.*—In looking back on the repeated attempts in the 18th century to construct a universal system of medicine it is impossible not to

[1] The itch is really an affection produced by the presence in the skin of a species of mite (*Acarus scabiei*), and when this is destroyed or removed the disease is at an end.

regret the waste of brilliant gifts and profound acquirements which they involved. It was fortunate, however, that the accumulation of positive knowledge in medicine did not cease. While Germany and Scotland, as the chief homes of abstract speculation, gave birth to most of the theories, progress in objective science was most marked in other countries,—in Italy first, and afterwards in England and France. We must retrace our steps a little to enumerate several distinguished names which, from the nature of the case, hardly admit of classification.

In Italy the tradition of the great anatomists and physiologists of the 17th century produced a series of accurate observers and practitioners. Among the first of these were Antonio Maria Valsalva (1666-1723), still better known as an anatomist; Giovanni Maria Lancisi (1654–1720), also an anatomist, the author of a classical work on the diseases of the heart and aneurisms; and Ippolito Francisco Albertini (1662–1738), whose researches on the same class of diseases were no less important.

In France Jean Baptiste Sénac (1693–1770) wrote also an important work on the affections of the heart. Sauvages, otherwise F. B. de Lacroix (1706–67), gave under the title *Nosologia Methodica* a natural-history classification of diseases; Jean Astruc (1684–1766) contributed to the knowledge of general diseases. But the state of medicine in that country till the end of the 18th century was unsatisfactory as compared with some other parts of Europe.

In England the brilliancy of the early part of the century in practical medicine was hardly maintained to the end, and presented indeed a certain contrast with the remarkable and unflagging progress of surgery in the same period. The roll of the College of Physicians does not furnish many distinguished names. Among these should be mentioned John Fothergill (1712–80), who investigated the "putrid sore throat" now called diphtheria, and the form of neuralgia popularly known as tic douloureux. A physician of Plymouth, John Huxham (1694–1768), made researches on epidemic fevers, in the spirit of Sydenham and Hippocrates, which are of the highest importance. William Heberden (1710–1801), a London physician, called by Samuel Johnson *ultimus Romanorum*, "the last of our learned physicians," left a rich legacy of practical observations in the *Commentaries* published after his death. More important in their results than any of these works were the discoveries of EDWARD JENNER (*q.v.*), respecting the prevention of small-pox by vaccination, in which he superseded the partially useful but dangerous practice of inoculation, which had been introduced into England in 1721. The history of this discovery need not be told here, but it may be pointed out that, apart from its practical importance, it has had great influence on the scientific study of infectious diseases. The name of John Pringle (1707–82) should also be mentioned as one of the first to study epidemics of fevers occurring in prisons and camps. His work entitled *Observations on the Diseases of an Army* was translated into many European languages, and became the standard authority on the subject.

In Germany the only important school of practical medicine was that of Vienna, as revived by Van Swieten (1700–72), a pupil of Boerhaave, under the patronage of Maria Theresa. Van Swieten's commentaries on the aphorisms of Boerhaave are thought more valuable than the original text. Other eminent names of the same school are Anton de Haen (1704–76), Anton Störck (1731–1803), Maximilian Stoll (1742–88), and John Peter Frank (1745–1821), father of Joseph Frank beforementioned as an adherent of the Brownian system, and like his son carried away for a time by the new doctrines. This, the old "Vienna School," was not distinguished for any notable discoveries, but for success in clinical teaching, and for its sound method of studying the actual facts of disease during life and after death, which largely contributed to the establishment of the "positive medicine" of the 19th century.

One novelty, however, of the first importance is due to a Vienna physician of the period, Leopold Avenbrugger (1722–1809), the inventor of the method of recognizing diseases of the chest by percussion. Avenbrugger's method was that of *direct* percussion with the tips of the fingers, not that which is now used, of *mediate* percussion with the intervention of a finger or plessimeter; but the results of his method were the same, and its value nearly as great. Avenbrugger's great work, the *Inventum Novum*, was published in 1761. The new practice was received at first with contempt and even ridicule, and afterwards by Stoll and Peter Frank with only grudging approval. It did not receive due recognition till 1808, when Corvisart translated the *Inventum Novum* into French, and Avenbrugger's method rapidly attained a European reputation. Surpassed, but not eclipsed, by the still more important art of auscultation introduced by Laennec, it is hardly too much to say that this simple and purely mechanical invention has had more influence on the development of modern medicine than all the "systems" evolved by the most brilliant intellects of the 18th century.

*Early Part of the 19th Century.*—It is not possible to carry the history of medicine, in a sketch such as this, beyond the early years of the 19th century, both because the mass of details becomes so large as to require more minute treatment, and because it is difficult as we approach our own times to preserve the necessary historical perspective. It was, however, in this period that what we regard as the modern school of medicine was formed, and took the shape which it has preserved to our own days. The characteristic of the modern school is the adoption in medicine of the methods of research of physical science, and the gradually declining importance attached to theory and abstract reasoning,—hypotheses, though not neglected, being used as means of research rather than as ultimate conclusions. Its method may therefore be called the positive method, or that of rational empiricism. The growth of the new school was first seen in two European countries, in France and England, and must be separately followed in the two. Germany entered the field later.

*Rise of the Positive School in France.*—The reform of medicine in France must be dated from the great intellectual awakening caused by the Revolution, but more definitely starts with the researches in anatomy and physiology of Marie François Xavier Bichat (1771–1802). The importance in science of Bichat's classical works, especially of the *Anatomie générale*, cannot be estimated here; we can only point out their value as supplying a new basis for pathology or the science of disease. Among the most ardent of his followers was François Joseph Victor Broussais (1772–1838), whose theoretical views, partly founded on those of Brown and partly on the so called vitalist school of Bordeu and Barthez, differed from these essentially in being avowedly based on anatomical observations. Broussais's chief aim was to find an anatomical basis for all diseases, but he is especially known for his attempt to explain all fevers as a consequence of irritation or inflammation of the intestinal canal (gastro-entérite). A number of other maladies, especially general diseases and those commonly regarded as nervous, were attributed to the same cause. It would be impossible now to trace the steps which led to this wild and long since exploded theory. It led, among other consequences, to an enormous misuse of bleeding. Leeches were his favourite

instruments, and so much so that he is said to have used 100,000 in his own hospital wards during one year. He was equalled if not surpassed in this excess by his follower Bouillaud, known for his important work on heart diseases. Broussais's system, to which he gave the name of "Médecine Physiologique" did much indirect good, in fixing attention upon morbid changes in the organs, and thus led to the rise of the strongly opposed anatomical and pathological school of Corvisart, Laennec, and Bayle.

Jean Nicolas Corvisart (1755–1821) has already been mentioned as the translator and introducer into France of Avenbrugger's work on percussion. He introduced some improvements in the method, but the only real advance was the introduction of mediate percussion by Piorry in 1828. The discovery had, however, yet to be completed by that of auscultation, or listening to sounds produced in the chest by breathing, the movements of the heart, &c. The combination of these methods constitutes what is now known as *physical diagnosis*. René Théophile Hyacinthe Laennec (1781–1826) was the inventor of this most important perhaps of all methods of medical research. Except for some trifling notices of sounds heard in certain diseases, this method was entirely new. It was definitely expounded in an almost complete form in his work *De l'auscultation médiate*, published in 1819. Laennec attached undue importance to the use of the stethoscope, and laid too much weight on specific signs of specific diseases; otherwise his method in its main features has remained unchanged. The result of his discovery was an entire revolution in the knowledge of diseases of the chest; but it would be a mistake to forget that an essential factor in this revolution was the simultaneous study of the condition of the diseased organs as seen after death. Without the latter, it is difficult to see how the information conveyed by sounds could ever have been verified. This increase of knowledge is therefore due, not to auscultation alone, but to auscultation combined with morbid anatomy. In the case of Laennec himself this qualification takes nothing from his fame, for he studied so minutely the relations of post-mortem appearances to symptoms during life that, had he not discovered auscultation, his researches in morbid anatomy would have made him famous. The pathologico-anatomical method was also followed with great zeal and success by Gaspard Laurent Bayle (1774–1816), whose researches on tubercle, and the changes of the lungs and other organs in consumption, are the foundation of most that has been done since his time. It was of course antecedent to the discovery of auscultation. Starting from these men arose a school of physicians who endeavoured to give to the study of symptoms the same precision as belonged to anatomical observations, and by the combination of both methods made a new era in clinical medicine. Among these were Chomel (1788–1858), Louis (1787–1872), Cruveilhier (1791–1874), and Andral (1797–1876). Louis, by his researches on pulmonary consumption and typhoid fever, had the chief merit of refuting the doctrines of Broussais. In another respect also he aided in establishing an exact science of medicine by the introduction of the numerical or statistical method. By this method only can the fallacies which are attendant on drawing conclusions from isolated cases be avoided; and thus the chief objection which has been made to regarding medicine as an inductive science has been removed. Louis's method was improved and systematized by Gavarret; and its utility is now universally recognized. Space does not permit us to trace further the history of this brilliant period of French medicine, during which the superiority of the school of Paris could hardly be contested. We can only mention the names of Bretonneau (1771–1862), Rostan (1790–1866), D'Alibert (1766–1837), Rayer (1793–1867), and Trousseau (1801–1866), the eloquent and popular teacher.

*English Medicine from* 1800 to 1840.—The progress of medicine in England during this period displays the same characteristics as at other times, viz., a gradual and uninterrupted development, without startling changes such as are caused by the sudden rise or fall of a new school. Hardly any theoretical system is of English birth; Erasmus Darwin (1731–1802), the grandfather of the great Charles Darwin, alone makes an exception. In his *Zoonomia* (1794) he expounded a theory of life and disease which had some resemblance to that of Brown, though arrived at (he says) by a different chain of reasoning.

Darwin's work shows, however, the tendency to connect medicine with physical science, which was an immediate consequence of the scientific discoveries of the end of the 18th century, when Priestley and Cavendish in England exercised the same influence as Lavoisier in France. The English school of medicine was also profoundly stirred by the teachings of the two brothers William and John Hunter, especially the latter,—who must therefore be briefly mentioned, though their own researches were chiefly concerned with subjects lying a little outside the limits of this sketch. William Hunter (1718–1783) was known in London as a brilliant teacher of anatomy and successful obstetric physician; his younger brother and pupil, John Hunter (1728–1793), was also a teacher of anatomy, and practised as a surgeon. His immense contributions to anatomy and pathology cannot be estimated here, but his services in stimulating research and training investigators belong to the history of general medicine. They are sufficiently evidenced by the fact that Jenner and Baillie were his pupils.

The same scientific bent is seen in the greater attention paid to morbid anatomy (which dates from Baillie), and the more scientific method of studying diseases. An instance of the latter is the work of Robert Willan (1757–1812) on diseases of the skin,—a department of medicine in which abstract and hypothetical views had been especially injurious. Willan, by following the natural-history method of Sydenham, at once put the study on a sound basis; and his work has been the starting point of the most important modern researches. About the same time William Charles Wells (1757–1817), a scientific investigator of remarkable power, and the author of a celebrated essay on dew, published observations on alterations in the urine, which, though little noticed at the time, were of great value as assisting in the important discovery made some years afterwards by Bright.

These observers, and others who cannot be mentioned here, belong to the period when English medicine was still little influenced by the French school. Shortly after 1815, however, when the Continent was again open to English travellers, many English doctors studied in Paris, and the discoveries of their great French contemporaries began to be known. The method of auscultation was soon introduced into this country by pupils of Laennec. John Forbes in 1824, and William Stokes of Dublin in 1825, published treatises on the use of the stethoscope. Forbes also translated the works of Laennec and Avenbrugger, and an entire revolution was soon effected in the knowledge of diseases of the chest. James Hope and Peter Mere Latham further developed this subject, and the former was also known for his researches in morbid anatomy. The combination of clinical and anatomical research led, as in the hands of the great French physicians, to important discoveries by English investigators. The discovery by Richard Bright (1789–1858) of the disease of the kidneys known by his name, has proved to be one of the most momentous of this century. It was published in *Reports of*

*Medical Cases*, 1827–31. Thomas Addison takes, somewhat later, a scarcely inferior place. The remarkable physiological discoveries of Bell and Marshall Hall for the first time rendered possible the discrimination of diseases of the spinal cord. Several of these physicians were also eminent for their clinical teaching,—an art in which Englishmen had up till then been greatly deficient.

Although many names of scarcely less note might be mentioned among the London physicians of the early part of the century, we must pass them over to consider the progress of medicine in Scotland and Ireland. In Edinburgh the admirable teaching of Cullen had raised the medical faculty to a height of prosperity of which his successor, James Gregory (1758–1821), was not unworthy. His nephew, William Pulteney Alison (1790–1859), was even more widely known. These great teachers maintained in the northern university a continuous tradition of successful teaching, which the difference in academical and other circumstances rendered hardly possible in London. Nor was the northern school wanting in special investigators, such as John Abercrombie, known for his work on diseases of the brain and spinal cord published in 1828, and many others. Turning to Ireland, it should be said that the Dublin school in this period produced two physicians of the highest distinction, Robert James Graves (*c.* 1800–1853) was a most eminent clinical teacher and observer, whose lectures are regarded as the model of clinical teaching, and indeed served as such to the most popular teacher of the Paris school in the middle of this century, Trousseau. William Stokes (1804–1878) was especially known for his works on diseases of the chest and of the heart, and for his clinical teaching.

*German Medicine from* 1800 *to* 1840.—Of the other countries of Europe, it is now only necessary to mention Germany. Here the chief home of positive medicine was still for a long time Vienna, where the "new Vienna school" continued and surpassed the glory of the old. Joseph Skoda (born 1805) extended, and in some respects corrected, the art of auscultation as left by Laennec. Karl Rokitansky (1804–1878), by his colossal labours, placed the science of morbid anatomy on a permanent basis, and enriched it by numerous discoveries of detail. Most of the ardent cultivators of this science in Germany in the next generation were his pupils. In the other German schools, though some great names might be found, as Romberg (1795–1873), the founder of the modern era in the study of nervous diseases, the general spirit was scholastic and the result barren, till the teaching of one man, whom the modern German physicians generally regard as the regenerator of scientific medicine in their country, made itself felt. Johann Lucas Schönlein (1793–1864) was first professor at Würzburg, afterwards at Zurich, and for twenty years at Berlin (from 1839–1859). Schönlein's positive contributions to medical science were not large but he made in 1839 one discovery, apparently small, but in reality most suggestive, namely, that the contagious disease of the head called favus is produced by the growth in the hair of a parasitic fungus. In this may be found the germ of the startling modern discoveries in parasitic diseases. His systematic doctrines founded the so-called "natural history school;" but his real merit was that of the founder or introducer of a method. In the words of Haeser, "Schönlein has the incontestable merit of having been the first to establish in Germany the exact method of the French and the English, and to impregnate this method with the vivifying spirit of German research." The name of Schönlein thus brings us to the threshold of the modern German school of medicine,—the most scientific and exact in Europe, and in its spirit strikingly in contrast with the theoretical subtlety of German systematists in the last century.

*Literature.*—The earliest work of authority on the history of medicine is that of Daniel le Clerc (*Histoire de la Médecine*, Geneva, 1696; Amsterdam, 1704, 1723, &c.), which ends with Galen. Freind's *History of Physick* (London, 1725–26, 2 vols.) carries on the subject from Galen to the beginning of the 16th century. The first complete history is that of Kurt Sprengel (*Versuch einer pragmatischen Geschichte der Arzneikunde*, Halle, 1792; 3d edition, Halle, 1821–28, 5 vols.; also in French, Paris, 1815). Beside these may be mentioned Hecker, *Geschichte der Heilkunde*, Berlin, 1822, and *Gesch. der neueren Heilkunde*, Berlin, 1839; Ch. Daremberg, *Histoire des sciences médicales*, Paris, 1870, 2 vols.; Edward Meryon, *History of Medicine*, London, 1861 (left unfinished, vol. i. only having appeared). The most recent and complete text-book is Haeser's *Lehrbuch der Geschichte der Medicin und der Epidemischen Krankheiten* (3d edition, Jena, 1875–79, 3 vols., in course of completion), to which the preceding sketch is very largely indebted.

In special departments of the subject the authorities are the following:—For classical medicine: Celsus, *De Medicina*; Littré, *Œuvres d'Hippocrate*, Paris, 1839–61, 10 vols. (especially vol. i.); Francis Adams, *Genuine Works of Hippocrates translated, with a Preliminary Discourse*, London (Syd. Soc.), 1849, and *Paulus Ægineta, translated, with a Commentary*, London (Syd. Soc.), 1844; Daremberg, *La Médecine dans Homère*, Paris, 1865, and *La Médecine entre Homère et Hippocrate*, Paris, 1869; and W. A. Greenhill's articles "Galen," "Hippocrates," &c., in Smith's *Classical Dictionary*, 1844. For Arabian medicine: Wüstenfeld, *Geschichte der Arabischen Aerzte und Naturforscher*, Göttingen, 1840; and Lucien Leclerc, *Histoire de la Médecine Arabe*, Paris, 1876, 2 vols. For Salernitan medicine: *Collectio Salernitana*, edited by De Renzi, Daremberg, &c., Naples, 1852, 5 vols.; *Regimen Sanitatis*, with introduction by Sir A. Croke, Oxford, 1830; and Daremberg, *L'Ecole de Salerne*, Paris, 1861. For medicine in England: John Aikin, *Biographical Memoirs of Medicine in Great Britain, to the time of Harvey*, London, 1780; *Lives of British Physicians*, London, 1830 (chiefly by Dr Macmichael, partly by Dr Bisset Hawkins and Dr H. H. Southey); and Munk, *Roll of the Royal College of Physicians of London*, 2d ed., 1878, 3 vols. For the modern schools: Hirschel, *Geschichte des Brown'schen Systems und der Erregungs Theorie*, Leipsic, 1846; Bouchut, *Histoire de la Médecine et des Doctrines Médicales*, 2 vols., Paris, 1873 (comparison of ancient and modern schools); Buckle, *History of Civilization in England*, 1858–61. (J. F. P.)

---

MEDINA, or rather EL-MEDÍNA (the city), or MEDÍNAT RASÚL ALLÁH (the city of the apostle of God), a town of the Hijáz in Arabia, in 25° N. lat., 40 E. long.,[1] the refuge of Mohammed on his flight from Mecca, and a renowned place of Moslem pilgrimage, consecrated by the possession of his tomb. The name El-Medína goes back to the Koran (*sûr.* xxxiii. 60); the old name was Yathrib, the Iathrippa of Ptolemy and Iathrippa of Stephanus Byzantius.

Medina stands in a sort of basin at the northern extremity of an elevated plain, on the western skirt of the mountain range which divides the Red Sea coast-lands from the central plateau of Arabia. At an hour's distance to the north it is dominated by Mount Ohod, an outlying spur of the great mountains, which is now visited by the pious as the scene of the well-known battle (see MOHAMMED), and the site of the tomb and mosque of the Prophet's uncle Hamza. To the east the plain is bounded by a long line of hills eight or ten hours distant, over which the Nejd road runs. A number of torrent courses (of which W. Kanát to the north, at the foot of Mount Ohod, and W. 'Akík, some miles to the south, are the most important) descend from the mountains, forming considerable streams and pools after rain, and converge in the

[1] This can only be viewed as a very rough estimate. The road from Yanbu' on the Red Sea, which runs somewhat north of east, is by Burton's estimate 132 miles. From Medina to Mecca by the inland or high road he makes 248 miles. The usual road near the coast by Rábigh and Kholeys and thence to W. Fátima cannot be very different in length. Caravans traverse it in about ten or eleven days.

neighbourhood of the town to unite farther west at a place called Zaghába, whence they descend to the sea through the "mountains of the Tihâma"—the rough country between Medina and its port of Yanbu'—under the name of W. Idam. Southwards from Medina the plain extends unbroken, but with a slight rise, as far as the eye can reach. The convergence of torrent courses in the neighbourhood of Medina makes this one of the best-watered spots in northern Arabia. The city lies close to one of the great volcanic centres of the peninsula, which was in violent eruption as late as 1266 A.D., when the lava stream approached within an hour's distance of the walls, and dammed up W. Kanát. The result of this and older prehistoric eruptions has been to confine the underground water, so important in Arabian tillage, which can be reached at any point of the oasis by sinking deep wells. Many of the wells are brackish, and the natural fertility of the volcanic soil is in many places impaired by the salt with which it is impregnated; but the date palm grows well everywhere, and the groves, interspersed with gardens and corn-fields, which surround the city on all sides except the west, have been famous from the time of the Prophet. Thus situated, Medina was originally a city of agriculturists, not like Mecca a city of merchants; nor, apart from the indispensable trade in provisions, has it ever acquired commercial importance like that which Mecca owes to the pilgrimage.[1] Landowners and cultivators are still a chief element in the population of the city and suburbs. The latter, who are called Nawákhila, and more or less openly profess the Shí'a opinions, form a sort of separate caste, marrying only among themselves. The townsmen proper, on the other hand, are a very motley race.[2] The mechanical arts, which the true Arab despises, are chiefly practised by foreigners. New settlers remain behind with each pilgrimage; and the many offices of profit connected with the mosque, the stipends paid by the sultan to every inhabitant, and the gains to be derived by pilgrim-cicerones (Muzawwirs) or by those who make it a business to say prayers at the Prophet's mosque for persons who send a fee from a distance, as well as the alms which the citizens are accustomed to collect when they go abroad, especially in Turkey, keep up an idle population greatly in excess of that which the district would naturally support in the present defective state of agriculture. The population of the city and suburbs may be from 16,000 to 20,000 souls.

The city proper is surrounded by a solid stone wall,[3] with towers and four massive gateways of good architecture, forming an irregular oval running to a kind of angle at the north-west, where stands the castle, held by a Turkish garrison. The houses are good stone buildings similar in style to those of Mecca; the streets are narrow but clean, and in part paved.[4] There is a copious supply of water conducted from a tepid source at the village of Ḳubá, 2 miles south, and distributed in underground cisterns in each quarter.[5] The glory of Medina, and the only important building, is the mosque of the Prophet, in the eastern part of the city, a spacious enclosed court between 400 and 500 feet in length from north to south, and two-thirds as much in breadth. The minarets and the lofty dome above the sacred graves are imposing features, but the circuit is hemmed in by houses or narrow lanes, and is not remarkable except for the principal gate (Báb el-Salám) at the southern end of the west front, facing the sacred graves, which is richly inlaid with marbles and fine tiles, and adorned with golden inscriptions. This gate leads into a deep portico, with ten rows of pillars, running along the southern wall. Near the further end of the portico, but not adjoining the walls, is a sort of doorless house or chamber hung with rich curtains, which is supposed to contain the graves of Mohammed, Abubekr, and 'Omar. To the north of this is a smaller chamber of the same kind, draped in black, which is said to represent the house or tomb of Fáṭima. Both are enclosed within an iron railing, so closely interwoven with brass wire-work that a glimpse of the so-called tombs can only be got through certain apertures where intercessory prayer is addressed to the prophet, and pious salutations are paid to the other saints.[6] The portico in front of the railing is not ineffective, at least by night light. It is paved with marble, and in the eastern part with mosaic, laid with rich carpets; the southern wall is clothed with marble pierced with windows of good stained glass, and the great railing has a striking aspect; but an air of tawdriness is imparted by the vulgar painting of the columns, especially in the space between the tomb and the pulpit, which has received, in accordance with a tradition of the Prophet, the name of the Garden (rauḍa), and is decorated with barbaric attempts to carry out this idea in colour.[7] The throng of visitors passing along the south wall from the Báb el-Salám to salute the tombs is separated from the Garden by a wooden partition about 8 feet high, painted in arabesques. The other three sides of the interior court have porticos of less depth and mean aspect, with three or four rows of pillars. Within the court are the well of the Prophet and some palm trees said to have been planted by Fáṭima.

The original mosque was a low building of brick roofed with palm branches, and much smaller than the present structure. The wooden pulpit from which Mohammed preached appears to have stood on the same place with the present pulpit in the middle of the south portico. The dwelling of the Prophet and the huts of his women adjoined the mosque. Mohammed died in the hut of 'Áisha, and was buried where he died; Abubekr and 'Omar were afterwards buried beside him. Now in 711 A.D. the mosque, which had previously been enlarged by 'Omar and 'Othmán, was entirely reconstructed on a grander scale and in Byzantine style by Greek and Coptic artificers at the command of the caliph Walíd and under the direction of 'Omar ibn 'Abd el-'Azíz. The enlarged plan included the huts above named, which were pulled down. Thus the place of the Prophet's burial was brought within the mosque; but the recorded discontent of the city at this step shows that the feeling which regards the tomb as the great glory of the mosque, and the pilgrimage to it as the most meritorious that can be undertaken except that to Mecca, was still quite unknown. It is not even certain

[1] The pilgrimage to Medina, though highly meritorious, is not obligatory, and it is not tied to a single season, so that there is no great concourse at one time, and no fair like that of Mecca.

[2] A small number of families in Mecca still claim to represent the ancient Ansár, the "defenders" of Mohammed. But in fact the old population emigrated *en masse* after the sack of Medina by Muslim in 683, and passed into Spain in the armies of Músá. In the 13th century one old man of the Khazraj and one old woman of the Aus tribe were all that remained of the old stock in Medina (Makkarí, i. 187; Dozy, *Mus. d'Espagne*, i. 111). The aristocratic family of the Beni Hoseyn, who claim descent from the martyr of Kerbela, and so from the Prophet, have apparently a better established pedigree.

[3] According to Ibn Khallikán (Slane's transl., iii. 927) the walls are of the 12th century, the work of Jamál el-Dín el-Isphahání.

[4] The Balát or great paved street of Medina, a very unusual feature in an Eastern town, dates from the 1st century of Islám. See Wüstenfeld's abstract of Samhúdí, p. 115.

[5] Kubá is famous as the place where the prophet lived before he entered Medina, and the site of the first mosque in which he prayed. It lies amidst orchards in the richest part of the oasis

[6] The space between the railing and the tomb is seldom entered except by the servants of the mosque. It contains the treasures of the mosque in jewels and plate, which were once very considerable but have been repeatedly plundered, last of all by the Wahhábís in the beginning of the present century.

[7] The word *rauda* also means a mausoleum, and is applied by Ibn Jubair to the tomb itself. Thus the tradition that the space between the pulpit and tomb was called by the Prophet one of the gardens of Paradise probably arose from a mistake.

what was done at this time to mark off the graves. Ibn Abd Rabbih, in the beginning of the 10th century (*Ikd*, Cairo ed., iii. 366), describes the enclosure as a hexagonal wall, rising within three cubits of the ceiling of the portico, clothed in marble for more than a man's height, and above that height daubed with the unguent called khalúk. This may be supplemented from Istakhrí, who calls it a lofty house without a door. That there are no gravestones or visible tombs within is certain from what is recorded of occasions when the place was opened up for repairs. Ibn Jubair (p. 193 *sq.*) and Samhúdí speak of a small casket adorned with silver, fixed in the eastern wall, which was supposed to be opposite the head of the Prophet, while a silver nail in the south wall indicated the point to which the corpse faced, and from which the salutation of worshippers was to be addressed (Burton misquotes). The European fable of the coffin suspended by magnets is totally unknown to Moslem tradition. The smaller chamber of Fátima is pretty modern. In the time of Ibn Jubair and of Ibn Batúta (unless the latter, as is so often the case, is merely copying his predecessor) there was only a small marble trough north of the rauda (or grave) which "is said to be the house of Fátima or her grave, but God only knows." It is more probable that Fátima was buried in the Bakí, where her tomb was also shown in the 12th century (Ibn Jubair, p. 198 *sq.*).

The mosque was again extended by El-Mahdí (781 A.D.), and was burned down in 1256. Of its appearance before the fire we have two authentic accounts by Ibn 'Abd Rabbih early in the 10th century, and by Ibn Jubair, who visited it in 1184. The old mosque had a much finer and more regular appearance than the present one; the interior walls were richly adorned with marble and mosaic arabesques of trees and the like, and the outer walls with stone marquetry; the pillars of the south portico (seventeen in each row) were in white plaster with gilt capitals, the other pillars were of marble. Ibn 'Abd Rabbih speaks of eighteen gates, of which in Ibn Jubair's time, as at present, all but four were walled up. There were then three minarets. After the fire which took place just at the time of the fall of the caliphate, the mosque long lay in a miserable condition. Its repair was chiefly due to the Egyptian sultans, especially to Káit Bey, whose restoration after a second fire in 1481 amounted almost to a complete reconstruction. Of the old building nothing seems to have remained but some of the columns and part of the walls; and, as the minarets have also been rebuilt and two new ones added, the architectural character is now essentially Egyptian. The great dome above the tomb, the railing round it, and the pulpit, all date from Káit Bey's restoration.

The suburbs, which occupy as much space as the city proper, and are partly walled in, lie south-west of the town, from which they are separated by an open space, the halting-place of caravans. Through the suburbs runs the watercourse called W. Buthán, a tributary of W. Kanát, which the Yanbu' road crosses by a stone bridge. The suburbs are the quarter of the peasants. Thirty or forty families with their cattle occupy a single courtyard (hósh), and form a kind of community often at feud with its neighbours. The several clans of Medina must have lived in much the same way at the time of the Prophet. The famous cemetery called Bakí' el-Gharkad, the resting-place of a multitude of the "companions" of the Prophet, lies immediately to the west of the city. It once contained many monuments, the chief of which are described by Ibn Jubair. Burckhardt in 1815 found it a mere waste, but some of the mosques have since been rebuilt.

*History.*—The story of the Amalekites in Yathrib and of their conquest by the Hebrews in the time of Moses is purely fabulous, see Nöldeke, *Ueber die Amalekiter*, 1864, p. 36. The oasis, when it first comes into the light of history, was held by Jews, among whom emigrants from Yemen afterwards settled. From the time of the flight of Mohammed (622 A.D.) till the Omayyads removed the seat of empire from Medina to Damascus, the town springs into historic prominence as the capital of the new power that so rapidly changed the fate of the East. Its fall was not less rapid and complete, and since the battle of Harra and the sack of the city in 683 it has never regained political importance. The history of Medina in this period will be told in the articles MOHAMMED and MOHAMMEDAN EMPIRE. Mohammed invested the country round Medina with an inviolable character like that of the Haram round Mecca; but this provision has never been observed with strictness. After the fall of the caliphs, who maintained a governor in Medina, the native emirs enjoyed a fluctuating measure of independence, interrupted by the aggressions of the sherifs of Mecca, or controlled by an intermittent Egyptian protectorate. The Turks after the conquest of Egypt held Medina for a time with a firmer hand; but their rule grew weak, and was almost nominal long before the Wahhábís took the city in 1804. A Turko-Egyptian force retook it in 1812, and the Turks still maintain a pasha with a military establishment, while the cadi and chief agha of the mosque (a eunuch) are sent from Constantinople. But the internal government is largely in Arab hands, and is said to be much better than that of Mecca.

*Sources.*—Medina has been described from personal observation by Burckhardt, who visited it in 1815, and Burton, who made the pilgrimage in 1853. Sadlier on his journey from Katíf to Yanbu' (1819) was not allowed to enter the holy city. Burckhardt was prevented by ill health from examining the city and country with his usual thoroughness. Little is added to our information by the report of 'Abd el-Razzák, who performed the pilgrimage in 1878, on a medical commission from the English Government. The chief Arabic authority besides Ibn 'Abd Rabbih and Ibn Jubair is Samhúdí, of whose history Wüstenfeld published an abstract in the Göttingen *Abhandlungen*, vol. ix., 1861. It goes down to the end of the 15th century. The topography of the country about Medina is interesting both historically and geographically; Bekrí, Yákút, and other Arabic geographers supply much material on this topic, but completer European accounts are wanting to permit of its full utilization. Medina now offers a more promising, but also a more perilous, field for an explorer than Mecca. (W. R. S.)

MEDINA SIDONIA, a town of Spain, in the province of Cadiz, and about 21 miles by road westward from that city, stands at a height of 600 feet above the sea-level, on an isolated hill surrounded by a cultivated plain. Apart from its picturesque airy situation it has nothing to interest the traveller; the streets are narrow, steep, and dirty, and its buildings and ruins are unimportant. The occupations of the inhabitants are connected chiefly with the agriculture and cattle-breeding carried on in the surrounding district; bricks and pottery are also made to some extent. The population in 1877 was 12,234.

Medina Sidonia has been identified by some with the *Asiao* of Pliny, but it is uncertain whether Jerez is not more probably the locality referred to by that name. Under the Visigoths the place was erected into a bishopric (Assidonia), and attained some importance; in the beginning of the 8th century it was taken by Tarik. In the time of Edrisi the province of Shadúna or Shidoua included, among other towns, Seville and Carmona; later Arab geographers place Shadúna in the province of Seville. The town gives its title to the ducal house of Guzman el Bueno, the hero of Tarifa (1292).

MEDITERRANEAN SEA. The southern shores of Europe are separated from the northern shores of Africa by the Mediterranean Sea. It extends in a generally east and west direction from longitude 5° 21′ W. to 36° 10′ E. Its length from Gibraltar to its eastern extremity in Syria is about 2100 miles. Its breadth is very various, being 400 miles from the mouth of the Rhone to the Algerian coast, 500 miles from the Gulf of Sidra to the entrance to the Adriatic, and 250 miles from the mouth of the Nile to the south coast of Asia Minor. From the very indented nature of its coasts, the general mass of the water is much cut up into separate seas, which have long borne distinctive names, as the Adriatic, the Ægean, the Sea of Marmora, the Black Sea, &c. The area of the whole system, including the Sea of Azoff, is given by Admiral Smythe as 1,149,287 square miles. If we deduct that of the Black Sea and Sea of Azoff, 172,506 square miles, we have for the area of the Mediterranean proper 976,781, or, roughly speaking, a million of square miles.

The Mediterranean is sharply divided into two great principal basins, the western and the eastern or Levant

basin. The western possesses a comparatively smooth and unindented coast-line. It is bounded on the south by the coast of Africa and the north coast of Sicily, and it is further enclosed by the coasts of Spain, France, and Italy, which form a roughly arc-shaped coast-line. There are comparatively few small islands in this basin, though some of the more important large ones occur in it. The eastern basin is by far the larger of the two, and extends from Cape Bon to the Syrian coast, including as important branches the Adriatic and the Ægean. The latter is connected directly, through the Hellespont, the Sea of Marmora, and the Bosphorus, with the Black Sea. The entrance to the western basin and to the sea generally from the ocean is through the Straits of Gibraltar in 36° N. lat. If this parallel be drawn out through the sea it will be found that the western basin lies almost wholly to the northward, and the main body of the eastern one to the southward of it, the mean latitude of the western basin being about 39° 30′, and that of the eastern basin 35°. They communicate with each other by the channels separating Sicily from Italy and from Africa. The former is known as the Strait of Messina, and is of insignificant size, the latter is a wide channel apparently without any distinctive name, and generally shallow. The greatest depth on the shallowest ridge reaching from the African to the Sicilian coast is under 200 fathoms, and agrees very closely with the corresponding depth at the entrance to the Straits of Gibraltar.

*Depth.*—So far as is at present known, the maximum depth is pretty nearly alike in the two basins, being 2040 fathoms in the western and 2150 fathoms in the eastern. Many lines of soundings have been run in the Mediterranean for telegraph purposes, and they afford a very good idea of the general configuration of the bottom. Between Marseilles and Algiers the depth ranges generally from 1200 to 1600 fathoms; between Naples and Sardinia from 1500 to 2000; between Alexandria and Rhodes from 1200 to 1600; and between Alexandria and Cyprus from 900 to 1100. The basin of the Mediterranean really begins about 50 miles to the westward of Gibraltar. It is here that the shallowest ridge stretches across from Africa to Spain; the maximum depth on it is probably not more than 180, and certainly less than 200 fathoms. From this ridge the bottom slopes quickly westward into the depths of the Atlantic, and gently eastward into the Mediterranean. The depth nowhere reaches 1000 fathoms until beyond Alboran Island, 120 miles east of Gibraltar. This is a small low island separated from the mainland on all sides by water of more than 400 fathoms; it must therefore be considered an oceanic as distinguished from a continental island.[1] Further to the north, and off the coast of Valencia, we have the Balearic Islands.—namely, Majorca, Minorca, Iviza, and Formentera. These also must be considered oceanic islands, and indeed two groups of oceanic islands. Iviza and Formentera are isolated both from the Spanish coast and from the other two islands by water of over 300 fathoms depth; Majorca and Minorca are connected by a bank with no more than 50 fathoms of water on it. Thirty miles east of Minorca there are more than 1400 fathoms; beyond that there are no soundings between the Baleares and the large and important group of Corsica and Sardinia. These islands are continental, being connected with the Italian mainland by the bank on which Elba occurs, and which is covered by little over 50 fathoms of water. The Straits of Bonifacio, which separate Corsica from Sardinia, are also quite shallow, so that Corsica and Sardinia may be looked on as a secondary peninsula attached to the Tuscan shore of Italy by a shallow bank not more than 15 or 20 miles broad, the deep water coming close up all round it. Almost the same may be said of Sicily, including the Malta group, but excluding the Lipari group, which is purely volcanic. From Cape Passaro, in the south-east end of Sicily, a line can be drawn connecting it with the town of Tripoli, and without passing over water of more than 300 fathoms. As has already been said, the west end of Sicily is connected with the coast of Tunis by a ridge in no part covered by more than 200 fathoms of water. Between these two ridges lies a small but comparatively deep basin of 600 to 700 fathoms. At the western extremity of it lies the mountainous island of Pantellaria. The bank on which Malta is situated stretches for nearly 100 miles in a southerly direction from Cape Passaro in Sicily. Opposite, on the African shore, is a similar bank of much larger dimensions, on which are the small islands Lampion and Lampedusa belonging to Italy. In the deep channel between them and Malta is the small but lofty island Limosa. It is entirely volcanic, with an extinct crater on its north-eastern side, and three smaller ones to the southward. It resembles the Lipari group off the north coast of Sicily, which rise abruptly out of deep water, being connected by no bank either with the African or the Sicilian coasts. Some of the Lipari group are still active, Stromboli and Vulcano being of the number. Off the south coast of Sicily, and between it and the island of Pantellaria, occurs the famous Graham's shoal, the remains of what was for a few weeks an island.[2]

The deepest water of the Mediterranean is found in its widest part between Malta and Crete, and the deep water comes close up to the Italian and Greek coasts, while on the African shore the water shoals more gradually. In the Strait of Messina, close to Reggio, there are depths of over 500 fathoms, and similar depths are found inside gulfs such as those of Taranto (nearly 1000 fathoms), of Corinth, Kalamata, and others. Also all through the Ægean in its many bights and channels very deep water is met with; in the Sea of Marmora we have 500 fathoms, and in the Black Sea over 1000 fathoms. All along the south coast of Asia Minor the water is very deep, and the large islands of Cyprus and Crete are both separated by very deep water from the mainland. If we take the eastern basin, and run along its western and southern coasts from the mouth of the Po along the shore of Italy, Sicily, and Africa to the mouth of the Nile, and even further along the Syrian shore, we do not find a single off-lying island of any importance except the Malta group, while all along the eastern and northern coasts from Trieste to Asia Minor the coast is deeply indented, and the water broken up by many large and important islands. These islands are grouped along the west coast of Turkey and Greece, and irregularly throughout the Ægean. The east coast of the Adriatic is studded with islands and inlets, and resembles in this respect the Ægean; the west coast, on the other hand, is low, and the water off it shallow, and there are few harbours. The Adriatic stretches in a north-westerly direction for about 460 miles from its entrance between

[1] Continental islands are those separated from the mainland by comparatively shallow seas, generally under 100 fathoms.

[2] With regard to its appearance and disappearance Admiral Smythe (*Mediterranean*, p. 111) says:—"It seems that, as early as the 28th of June 1831, Captain Swinburne, in passing nearly over the spot, felt several shocks of a sea-quake, proving that the cause was then in operation; but on the 19th of the following July the crater had accumulated to a few feet above the level of the sea, and was in great activity, emitting vast volumes of steam, ashes, and scoriæ. From that time it gradually increased in all its dimensions till towards the end of August its circumference was about 3240 feet and its height 107; then from October various changes took place, and it entirely disappeared in December." Since that time it has changed considerably. In 1863 the least water on it was 15 feet. It has two heads close together, and at the distance of about 20 yards all round there are from 7 to 9 fathoms of water.

Cape Sta Maria di Leuca and the island of Corfu to the Venetian shore in the Gulf of Trieste. Its average width is about 100 miles. A ridge with little over 400 fathoms appears to run across its entrance. Inside this the water reaches a depth of 765 fathoms, but shoals again rapidly towards Pelagosa Island, from which to the northward, including quite two-thirds of the sea, the depth is under 100 fathoms; indeed no part of the sea within 150 miles of its northern extremity is over 50 fathoms deep. There is authentic historical evidence of the encroachment of the Italian shores on the Adriatic, causing thereby a diminution of its area. As a consequence many towns which were once thriving seaports are now many miles inland; thus Adria, which was a station of the Roman fleet, is now 15 miles inland, and there are many similar examples. The large rivers Po and Adige, which bring the drainage of the southern slopes of the Alps to the sea, deliver large quantities of sediment in the course of the year. The distribution of this mud is affected, not only by its own weight tending to make it sink to the bottom, but also by the set of the currents, which, running up the eastern coast, turn to the westward and southward at the upper end of the sea, and so tend to distribute the river mud along the bottom in the neighbourhood of the Italian coasts. The fact that towns which were formerly seaports are now inland does not therefore necessitate the assumption of a general rise of the land, it is merely a reclamation by natural agencies of land from the sea at the expense of the inland mountainous country. Precisely similar phenomena are observed in the neighbourhood of the mouths of the Rhone and of the Nile.

*Specific Gravity, Currents, &c.*—On the specific gravity Dr Carpenter reports many and interesting observations. In round numbers, that of the surface-water of the Atlantic off the Straits of Gibraltar is 1·0260 to 1·0270, that of the western basin of the Mediterranean 1·0280 to 1·0290, and that of the eastern basin 1·0290 to 1·0300, while that of the Black Sea is 1·0120 to 1·0140. It will thus be seen that the water of the Mediterranean proper is very much salter than either the Atlantic on the west or the Black Sea on the east, and this great density of the water affords a useful means of recognizing it when investigating the interchange of waters which takes place at the two extremities of the sea. Both the temperature and the specific gravity of the water are evidences of the local climate. The great concentration of the water shows how dry the atmosphere at the surface must be, and how insignificant the contributions of fresh water. With regard to the balance existing between the two factors, evaporation and precipitation, it would be impossible to give figures with any claim to accuracy, but a rough estimate may be formed by taking such data as Fischer has given. He puts the rainfall over the whole Mediterranean drainage area at 759·4 millimetres, or almost exactly 30 inches. If we remember that the average rainfall of the eastern slopes of Great Britain is less than 30 inches, and that therefore this may be taken as the maximum yearly supply to the North Sea, we may be sure that the Mediterranean does not receive more than 30 inches of fresh water in the year. With regard to the rate of evaporation over the area of the Mediterranean there is but very meagre information, but wherever it has been observed it has been found to exceed the rainfall, even as much as three times. Thus at Madrid it is 65 inches, or more than four times the rainfall, at Rome 105 inches, and at Cairo 92 inches. It may therefore without exaggeration be assumed that the evaporation is at least twice as great as the precipitation. Putting the latter at 30 inches, we should have 60 inches for the yearly evaporation, and a balance of 30 inches evaporation over precipitation. Were there no provision for making good this deficiency, the level of the Mediterranean would sink until its surface was so far contracted as to lose no more by evaporation than would be supplied by rain. This condition would probably not be fulfilled before all the Ægean and Adriatic and the whole of the western basin west of the island of Sardinia were laid dry, and what is now the Mediterranean would be reduced to two "Dead Seas," one between Sardinia and Naples and the other between Africa and the mouth of the Adriatic. That the level and the salinity of the Mediterranean remain constant is due to the supply of water which enters at the Straits of Gibraltar. The currents in this passage have frequently engaged attention both from their scientific and their nautical interest. The most detailed investigation was that carried out by Captain Nares and Dr Carpenter in H.M.S. "Shearwater" in the year 1871.[1] From these investigations it appears that there are usually two currents in the Straits at the same time, one superposed on the other. Both are affected by tidal influence, but, after allowing for it, there is still a balance of inflow in the upper and of outflow in the under current. The waters of the two currents are sharply distinguished from each other by their salinity. Further, the upper current appears to affect by preference the middle of the channel and the African coast, while the under current appears to crop out at the surface on the Spanish coast. This distribution, however, is much modified by the state of the tide, and it must be remembered that in such places the surface separating the upper and under currents is rarely, if ever, a horizontal plane. That there is a balance of outflow over inflow at the bottom was well shown by the result of soundings as much as 200 miles north-west of the entrance of the Straits, where, in a depth of 1560 fathoms, water of decided Mediterranean origin was got from the bottom. There can be no doubt that this outflow of warm and dense Mediterranean water is largely instrumental in causing the comparatively very high bottom temperature in the eastern basin of the North Atlantic.

We have assumed that the balance of water removed by evaporation is 30 inches, or 2·5 feet. If we take the area of the Mediterranean to be 1,000,000 square miles, we have the volume of water removed—

$$v = 2{\cdot}5 \times 36 \times 10^{12} = 90 \times 10^{12} \text{ cubic feet.}$$

This quantity of water has to be supplied from the Atlantic without raising the total quantity of salt in the sea. We have seen that the only provision for the removal of the surplus salt is the outward under current in the Straits. Hence the inward upper current must be sufficient to replace the water lost both by evaporation and by the outflow of the under current. We may take the Atlantic water to contain 3·6 per cent. and the Mediterranean to contain 3·9 per cent. of salt. In order that the under current may remove exactly as much salt as is brought in by the upper one, their volumes must be in the inverse ratio of their saline contents, or the volume of the upper current must be to that of the under one in the ratio 39 : 36 or 1000 : 923; so that only 7·7 per cent. of the inflow goes to replace the water removed by evaporation, while the remaining 92·3 per cent. replaces the water of the under current. We have then for the total volume of the inward current per annum

$$V = \frac{100}{7{\cdot}7} v = 1170 \times 10^{12} \text{ cubic feet.}$$

The width of the Straits from Tarifa to Point Cires is 8 miles, or 48,000 feet, and the average depth of the stream may fairly be taken as 100 fathoms; hence the sectional area is in round numbers 29,000,000 square feet.

[1] *Proc. Roy. Soc.* (1872), xx. 97, 414.

Dividing the volume by the area we have for the mean annual flow

$$R=\frac{1170\times10^{12}}{29\times10^{6}}=40\times10^{6}\text{ feet.}$$

Reducing this to miles per day, we find that if the above data are correct the inflowing current at the Straits of Gibraltar ought to be equivalent to a current 8 miles wide, 100 fathoms deep, and running with the uniform velocity of 18·3 miles in twenty-four hours. As the currents are reversed with the tides this is the balance of inflow over outflow in the upper current. It is worthy of remark that the flood tide runs to the westward at the surface and the ebb to the eastward. The following table of tides at places inside and outside the Straits will show that the mere differences of level due to the different tidal ranges at adjacent localities are sufficient to cause strong local currents.

| Places. | High Water. Full and Change. | Springs Rise. | Neaps Rise. | Neaps Range. |
|---|---|---|---|---|
| | H. M. | Ft. in. | Ft. in. | Ft. in. |
| Chipiona | 1 30 | 12 5 | 8 0 | 3 6 |

| Rabat | 1 46 | 11 0 | 7 1 | 3 3 |
| Mogador | 1 18 | 12 4 | 8 0 | 3 6 |

A similar phenomenon is witnessed at the other end of the sea. Here the fresher waters of the Black Sea rush in through the narrow channel of the Dardanelles, causing a surface inflow of comparatively fresh water, while there is an outflow below of denser Mediterranean water. The dimensions of the Straits are too small to make the phenomenon of any importance for the supply of the Mediterranean. The conditions both in the Dardanelles and in the Bosphorus were examined very carefully in the year 1872 by Captain Wharton, R.N., of H.M.S. "Shearwater," and his results are published in an interesting report to the admiralty, of that date. It is remarkable that the comparatively fresh water of the Black Sea persists without sensible mixture through the Sea of Marmora and into the Dardanelles, while there is constantly a current of Mediterranean water running underneath, and the depth in the two channels is only from 30 to 50 fathoms. There can be little doubt that the saltness of the Black Sea is due wholly to the return current of Mediterranean water entering through the Bosphorus. Were the exit of the Black Sea a channel with sufficient fall to bring the surface of the Sea of Marmora below the level of the highest part of its bottom, so that no return current could take place, the waters of the Black Sea would be fresh.

In the body of the sea the rise and fall are much less than at any of the places in the above table. At Algiers a self-recording tide gauge was set up by Aimé, and from its records he deduced a rise and fall of 88 millim. (say 3½ in.) at springs and half that amount at neaps, a fluctuation which would escape ordinary observation, as it would be masked by the effects of atmospheric disturbances. At Venice and in the upper reaches of the Adriatic, the true lunisolar tide seems to be more accentuated than in other parts; but here also its effects are subordinate to those of the wind. In summer the Mediterranean is within the northern limit of the north-east trade wind: consequently, throughout a great part of the year, the winds are tolerably constant in direction; and, blowing as they do over large areas of water, they are instrumental in moving large masses of it from one point to another, and so producing streams and currents.

The effect of wind on a surface of water is twofold: it produces the rhythmic motion of waves and the motion of translation of currents. Besides the motion produced by the direct action of the wind on the surface-water, there are currents due in the first instance to the accumulation of water produced by a wind which has been blowing constantly in one direction. The phenomenon of an abnormally high tidal rise with a gale of wind blowing on shore is one with which inhabitants of the British Islands are familiar. It is also a matter of frequent observation that, for instance, a south-west gale which exaggerates the height of high water on the western coasts of Britain reduces it on the east coasts. It blows the water on the west coast and off the east coast, so that the difference in the high-water levels on the two coasts is very pronounced. Supposing free communication were quickly made between the two coasts, a current would be the result, and its violence would be much greater than would be due to the local action of the wind on its surface. In the Mediterranean the winds blow during a great portion of the year very constantly from one direction or another, and generally from north and east. The extent of the sea is so great that the slope produced by the transference of the surface water constantly in one direction might have a sine or arc capable of being measured in feet and inches when the radius is as much as 200 miles long. Thus at Port Mahon, in the island of Minorca, according to the *Admiralty Sailing Directions*, the water rises and falls according to the direction of the wind. With wind from south-east or south-west the water rises, but from north-west or north-east it falls. When northerly or north-westerly winds prevail, and this is the case for two-thirds of the year, a strong current sets to the south-west off Ayre Island, which is reversed in seasons when south-westerly winds prevail. This current is due to the water escaping round the end of Minorca having been driven southward so as to raise a head on the north coasts of the island. Similarly in the Faro or Strait of Messina the currents, of which the famous Scylla and Charybdis are swirls or eddies, are the evidence of a tendency towards equalizing the levels of the eastern extremity of the western basin and of the western extremity of the eastern basin. In addition to this peculiarity of position with reference to the two basins, it has been found that there is a very strong purely tidal influence at work which alone produces an alteration in the direction of the currents, and thus adds to the confusion of the waters. At Capo di Faro the rise is scarcely perceptible, at Messina it may attain a maximum of 10 to 13 inches. In the Straits of Bonifacio, between Corsica and Sardinia, the currents follow entirely the direction of the prevailing winds, and are at times very rapid. In the channel between Sicily and the African coast the currents also follow the winds. In long periods of calm weather a steady easterly set is observed, no doubt a prolongation or reproduction of the Gibraltar current.

*Temperature.*—Nothing whatever was known of the temperature of the deep water of the Mediterranean until Saussure extended to it his classical investigation into that of the Swiss lakes. In October 1780 he sank his thermometer to a depth of 160 fathoms off Genoa and of 320 fathoms off Nice, and at both depths he found the temperature of the water to be 55°·8 F. These observations have a special value, for, owing to Saussure's method of experimenting, his results were not affected by the pressure obtaining at great depths in the sea. Fifty years elapsed before any similar experiments were made, when D'Urville, in the "Astrolabe," made a few observations at the beginning and the end of his famous expedition. There is some uncertainty about his observations in 1826 and 1829, and also about the later ones of Bérard in 1831, as

we are not informed whether the self-registering instruments used were protected from pressure or not. Mr Prestwich,[1] however, who has collected and critically discussed all the older deep-sea temperature observations, concludes, from a comparison of their results with those obtained by Aimé with protected instruments, that they were so protected, and admits their results into his tables without correction. In the deep water to the northward of the Balearic Islands D'Urville found in April 1826 54°·5 F. in 270 fathoms, and in March 1829 54°·7 at the same depth, and the same temperature (54°·7) in 530 fathoms. Bérard, experimenting in the sea between the Balearic Islands and Algeria, found the temperature of the deep water nearly a degree higher, namely 55°·4 F., in depths of 500 to 1000 fathoms. Aimé[2] relates his own careful experiments on the temperature of both surface and deeper water in the neighbourhood of Algiers, and discusses them in connexion with those of other observers with very great ability. He concludes from his own observations and those of Bérard that the uniform temperature at great depths is 54°·86 F. From a consideration of the general climate of the Mediterranean, he comes to the conclusion that the temperature in the deeper layers of the sea ought to be lower than the annual mean of the surface, and that it ought to be not very different from the mean surface temperature in the winter months. From observations at Toulon and Algiers, he finds that at neither place does the surface temperature fall below 50° F., and that the mean surface temperatures in the months December, January, February, March, and April is at Toulon 53°·06 F. and at Algiers 56°·84 F. The mean of these two temperatures is 54°·9 F., which is almost exactly what he finds to be the mean annual temperature of the deepest water of the western basin. During the forty years which have elapsed since Aimé made his experiments and speculations, further observations have only tended to confirm his theory. It is true that the temperatures observed in the many soundings which have been made of late years have not shown absolute identity of temperature, and it is probable that the greater the refinement in the instruments used the more decided will the local differences appear. Especially it will be apparent that the bottom temperature varies with the climate of the preceding winter, and the distribution of temperature varies much with the prevalence of the winds. At the few stations where the temperature of the sea-water and that of the air are regularly examined, it appears that the water is generally for the greater part of the year warmer than the air, and in winter considerably so. The existing observations, however, are too few to justify any very definite statement on the subject. At Palermo the sea is warmer than the air throughout the whole year with the exception of the months May and June. In Algiers Aimé found but little difference; in autumn and winter the water was slightly warmer, in spring and summer slightly colder, than the air. In the eastern basin we have first Admiral Spratt's observations in July 1845 in Ægina Gulf. In all his experiments made previous to the year 1860 he determined the temperature of the bottom water by taking that of the mud brought up in the dredge. This is a very excellent method; in fact it is probably the best of all methods if a sufficient quantity of mud be obtained. From 1860 he used self-registering unprotected thermometers, which gave results necessarily too high, and it is impossible to apply any reliable correction to them without experimentally determining it on each thermometer which was used. By the first method Admiral Spratt found 55°·5 F. at depths between 100 and 200 fathoms.

From these observations it seemed reasonable to conclude, as Aimé had done, that all over the Mediterranean a practically uniform temperature is found at all depths greater than 100 or 200 fathoms, and that this temperature is 54° to 56° F. In order thoroughly to investigate this matter, as well as the biological conditions of the deep water of the Mediterranean, H.M.S. "Porcupine," Captain Calver, with Messrs Carpenter and Gwyn Jeffreys, visited the western basin of the Mediterranean in the autumn of 1870. A large number of temperature observations were made in the western basin near its southern coasts, and one sounding with temperature observation in the eastern basin a short distance from the Sicilian coast, the result of which was to confirm the conclusion arrived at from earlier observations, that, however high the temperature of the surface may be (and it may reach 90° F.), the water becomes rapidly cooler as we go below the surface until we reach a depth of about 100 fathoms, where a temperature of 54° to 56° F. is found, and persists without sensible variation to the greatest depths. The average of all the bottom temperatures in the western basin was 54°·88 F. Three soundings were made in the intermediate basin to the eastward of Pantellaria in depths of 266, 390, and 445 fathoms, and in each case the bottom temperature was found to be 56°·5 F., or about a degree and a half warmer than in the deeper western basin. This is precisely what might have been expected from what we know of inland seas divided into several basins. In summer the shallower basin has usually a higher temperature at the bottom than is found at the same depth in the deeper one. Only one observation was made in the eastern basin, namely off Cape Passaro, in 1743 fathoms, with a bottom temperature of 56°·0 F. That the temperature in this basin should be lower than in the Pantelleria basin is due to its greater depth, and that it should be higher than is found in the western basin is due to its lower latitude. These researches were further prosecuted in the autumn of 1871 in the "Shearwater." Captain Nares, accompanied by Dr Carpenter. At two stations in the eastern basin "serial temperatures" were taken. At the first, 35° 54′ N. lat., 16° 23′ E. long., depth 1650 fathoms, the bottom temperature was 56°, or the same as had been observed the year before in 1743 fathoms; at the second, 32° 17½′ N. lat., 26° 44′ E. long., depth 1970 fathoms, the bottom temperature was 56°·7, and the temperature at all intermediate depths was much higher than at the first station. The mean temperature of the water from the surface to a depth of 200 fathoms was, at the first station, 63°·75 F., and at the second 66°·78 F., or three degrees higher. At the first station all the temperatures down to 100 fathoms are higher than were observed in 1870 in the western basin, but it must be remembered that temperature observations made in different years cannot with justice be closely compared, as the climates of the two years are sure to differ considerably, and in the present case the difference in climate between the summers of 1870 and 1871 appears to have been very considerable.

In the autumn of 1881 a very interesting series of observations were made by Captain Magnaghi, hydrographer of the Italian navy, and Professor Giglioli, on board the Italian surveying ship "Washington," in that part of the western basin which is enclosed between the islands Corsica and Sardinia on the one side and the Italian coasts on the other. It is here that the deepest water of the western basin was found; and, apart from the great interest attaching to the physical results obtained, the collections made with the dredge in the comparatively lifeless waters were of the very highest importance, showing, as they did, a practical identity in the abyssal fauna with that of the open ocean. This is the more remarkable as we have hitherto been accustomed to consider the similarity in the fauna of portions of the ocean remotely distant from each other as being due to the likeness of their temperatures. In the Mediterranean, however, the bottom temperature is quite 20° F. higher than is found in great depths anywhere in the open ocean.

For determining the temperature of the deep water Captain Magnaghi used the half-turn reversing thermometer of Negretti and Zambra, which in itself is a very beautiful instrument. The mechanical arrangement, however, for reversing, even as improved by Magnaghi, was not so satisfactory, and from certain irregularities in the temperature observations reported the writer is inclined to think that some of the remarkable results obtained, for instance on the 11th August, are due to this instrumental imperfection. On that day the water at 70 metres was found to have a temperature of 25°·1 C., while that at 50 metres was 20°·1 C., and that at 90 metres was 16°·7 C. The results obtained in the deep water are no doubt quite reliable, for the temperature is so uniform that a few fathoms more or less in the depth at which it turned would make no difference in the temperature registered. In the more northern parts of this portion of the western basin, off the coast of Corsica, we find a practically uniform temperature from 250 metres down to the bottom in 2800 metres, the mean bottom temperature being 55°·96 F. Further to the south the temperature of the abyssal water appears to be distinctly higher. Thus between the south end of Sardinia and the Bay of Naples, in the deepest water, the practical uniformity of temperature is not reached until a depth of 1000 metres has been passed, and it is there 56°·7 F. It is unfortunate that we do not know what the bottom temperature in other parts of the Mediterranean was. In this summer of 1881 it was quite one degree higher than that observed by Dr Carpenter in 1870.

The great value of such a volume of water as an equalizer of temperature on its shores must be apparent, though in this respect it is inferior to the Atlantic Ocean in its immediate neighbourhood. Places on the west coast of Spain and Portugal have a much higher winter temperature and lower summer temperature than places in the same latitude in Italy. The reason of this is simple: on the Atlantic coast the principal winds in winter are from the south-west, and have a warming effect, while in summer the source of the north-east trade wind is pushed back into the Bay of Biscay, causing in this season constant northerly winds along the coast of Portugal. The winds of the Mediterranean have no seas of remote latitudes to draw on either for heating or cooling purposes, though the sandy deserts of Africa which bound its southern coasts have at certain seasons a very decided influence on the climate. The tempering action of the sea does not extend very far inland, as is evident from the climate of inland towns in Italy. As the Mediterranean shores have so much importance as health-resorts, the data presented in the following table are of interest. They are taken chiefly from Theobald Fischer's *Studien über das Klima der Mittelmeerländer*.

*Nature of the Bottom.*—In the western basin the bottom consists chiefly of clay of a grey to brownish colour. Without doubt, when freshly collected, the surface layer is reddish-brown and the lower ones dark grey. There is always some carbonate of lime, chiefly due to *Foraminifera*. The mud very much resembles that obtained from similar depths in those parts of the open ocean whose bottom waters are shut off from free communication by ridges which may not approach within 2000 or 1500 fathoms of the surface, and with the exception of the *Foraminifera* it much resembles the mud from enclosed and comparatively shallow basins off the west coast of Scotland. In the following table the analyses are given of a few samples on the line of the submarine cable connecting Marseilles with Algiers.

To the student of the physical conditions of the sea the Mediterranean possesses a very high interest; its size is such as to entitle it to rank among oceans, while it is so completely cut off from the remaining world of water that it presents us with a type which is purely local, and one might almost say provincial. (J. Y. B.)

MEDLAR, *Mespilus Germanica*, L., of the tribe *Pomeæ* of the order *Rosaceæ*, regarded by Bentham and Hooker as a subgenus of *Pyrus* (*Gen. Pl.*, i. 626; see also DC., *Prod*, ii. 633; *Trans. Lin. Soc.*, xiii. 99), is a native of European woods, &c., from Holland southwards, and of western Asia (Loudon, *Arb.*, ii. 877). It occurs in hedges, &c., in middle and south England, as a small much-branched spinous tree, but is not indigenous to Great Britain (Hooker's *Stud. Fl. of Br. Isles*, 132; Baxter's *Brit. Gen. of Pl.*, 493, and *Mag. Nat. Hist.*, vol. ix. 86). The medlar was well known to the ancients. Pickering (*Chron. Hist. of Pl.*, 201) identifies it with a tree mentioned in a Siao-ya ode (*She-King*, ii. 1, 2), 827 B.C. It is the *μεσπίλη* of Theophrastus and *Mespilus* of Pliny. Loudon (*l.c.*) gives three varieties, *diffusa*, *stricta*, and *sylvestris*,—the last being spiny, but losing its spines under cultivation,—as well as four varieties of fruit. He also mentions several instances of large specimens throughout England. The well-known fruit is globular, but depressed above, with leafy persistent sepals, and contains stones of a hemispherical shape. It is not fit to eat until it begins to decay. (For culture of the medlar see HORTICULTURE.) The Japanese medlar is *Eriobotrya japonica*, L, a genus of the same tribe of *Rosaceæ*.

MÉDOC is the name given to the district in France adjoining the left bank of the Gironde from Ambès, the point where the Garonne and Dordogne unite, to Lesparre, where the marshes and polders which border on the mouth of the river begin; its length varies from 35 to 40 miles, its breadth from 12 to 5, and the area is about 386 square miles. It is formed by a number of low hills, which separate the Landes from the Gironde, and is traversed only by small streams; the Gironde itself is muddy, and often enveloped in fog, and the region as a whole is very far from being picturesque; but a fifth part of its soil is occupied by vineyards, the products of which form the finest growths of Bordeaux. Of these the most esteemed are Château-Margaux, Château-Laffitte, and Château-Latour. Prior to the ravages of the *Phylloxera*, the annual product of the Médoc district was 40,000 tuns, of which 9000 were of fine quality.

MEDUSA. See GORGON, vol. x. p. 785. See also HYDROZOA, vol. xii. p. 547 *sq.*

MEDYN, a district town of Russia, situated in the government of Kaluga, 39 miles north-west of the capital of the province, on the highway from Moscow to Warsaw. It was formerly known under the name of Mezetsk, and in the 14th century formed part of the Smolensk principality. The soil of the surrounding country being rather infertile, the population is engaged to some extent in manufactures of linen, cotton, and paper, and the merchants of Medyn carry on a brisk trade in this produce, as well as in rye, oats, and hemp seed. The population is 8000.

MEER, JAN VAN DER (1632–1675), of Delft,—not to be confounded with the elder or younger Van der Meer of Haarlem or with Van der Meer of Utrecht,—is one of the excellent painters of Holland about whom the Dutch biographers give us little information.[1] Van der Meer, or Vermeer, by which name he is also known, was born in Delft in 1632. There is a tradition, handed down by the Dutch writers, that he was a pupil of Carel Fabritius, but, in the strict sense of the word, this is almost impossible, for Fabritius was but eight years older than Van der Meer, and entered the guild of St Luke only one year before our painter. From his early death the works by Fabritius are few, but his contemporaries speak of him as a man of remarkable power, and the paintings now ascertained to be from his hand, and till recently ascribed to Rembrandt, prove him to have been deeply imbued with the spirit and manner of that master. Whether Van der Meer had ever any closer relation to Rembrandt than through companionship with Fabritius remains as yet uncertain. In 1653 he married Catherine Bolenes, and in the same year he entered the guild of St Luke of Delft, becoming one of the heads of the guild in 1662, and again in 1670. He died at Delft in 1675, leaving a widow and eight children. His circumstances cannot have been flourishing, for at his death he left twenty-six pictures undisposed of, and his widow had to apply to the court of insolvency to be placed under a curator, who, it is interesting to know, was Leeuwenhoek, the naturalist.

It is his works, however, that claim our attention. For more than two centuries he has been almost completely forgotten, and his pictures have been sold under the names

[1] This undeserved neglect seems to have fallen on him at an early period, for Houbraken (*Groote Schouburgh*, 1718), writing little more than forty years after his death, does not even mention him. The only definite information we have from a contemporary is given by Bleyswijck (*Beschrijving der Stad Delft*. 1687), who tells us that he was born in 1632, and that he worked along with Carl Fabritius, an able disciple of Rembrandt, who lost his life by an explosion of a powder magazine in Delft in 1654. It is to the patient researches of W. Bürger (Th. Dorè), Havard, Obreen, Soutendam, and others that we owe our knowledge of the main facts of his life, discovered in the archives of his native town.

and forged signatures of the more popular De Hooch, Metzu, Terborch, and even of Rembrandt. The honour of first recalling the attention of the art-world to this most original painter belongs undoubtedly to Thoré, an exiled Frenchman, who described his then known works in his *Musées de la Hollande* (1858–60), published under the assumed name of W. Bürger. The result of his researches, continued in his *Galerie Suermondt* and *Galerie d'Arenberg*, was afterwards given by him in a charming, though incomplete, monograph (*Gazette des Beaux-Arts*, 1866, pp. 297, 458, 542). The task has since been prosecuted with success by Havard (*Les Artistes Hollandais*), and by Obreen (*Nederlandsche Kunstgeschiedenis*, Dl. iv.), and we are now in a position to refer to Van der Meer's works. His pictures are rarely dated, but, luckily for us, one of the most important bears the date 1656, and thus gives us a key to his styles. The picture referred to is the only one that has figures of life size. It is the Woman and Soldier, with other two figures, of the Dresden gallery, and is painted with remarkable power and boldness, great command over the resources of colour, and with wonderful expression of life. For strength and colour it more than holds its own beside the neighbouring Rembrandts. To this early period of his career belong, from internal evidence, the Reading Girl of the same gallery, the luminous and masterly view of Delft in the museum of the Hague, La Laitière and the small street view, both in the collection of M. Six van Hillegom at Amsterdam, Le Soldat et la Fillette qui Rit of M. Double, the Country House in the gallery at Berlin, and others. In all these we find the same brilliant style and vigorous work, a solid impasto and a crisp sparkling touch. His first manner seems to have been influenced by the pleiad of painters circling round Rembrandt, a school which we know lost favour in Holland in the last quarter of the century. During the last ten or twelve years of his life Van der Meer adopted a second manner. We now find his painting smooth and thin, and his colours paler and softer. Instead of masculine vigour we have refined delicacy and subtlety, but in both styles beauty of tone and perfect harmony are conspicuous. Through all his work may be traced his love of lemon-yellow and of blue of all shades. Of his second style typical examples are to be seen in La Coquette of the Brunswick gallery, in the Woman Reading in the Van der Hoop collection at the Hague, in the Lady at a Casement belonging to Lord Powerscourt (exhibited at Burlington House, 1878), and in the Music Master and Pupil belonging to the Queen (exhibited at Burlington House, 1876).

Van der Meer's works are extremely rare. There is but one in the Louvre, the Lace Maker; Dresden has the two above-mentioned, while Berlin has three, all acquired in the Suermondt collection, and the Czernin gallery of Vienna is fortunate in possessing a fine picture, believed to represent the artist in his studio. In the Arenberg gallery at Brussels there is a remarkable head of a girl, half the size of life, which seems to be intermediate between his two styles. Several of his paintings are to be found in private foreign collections. In all his work there is a singular completeness and charm. In rendering momentary expression he is a master, and his pictures attract by the perfect delineation of character as well as by the technical skill of the painter. His tone is usually silvery with pearly shadows, and the lighting of his interiors is equal and natural. In all cases his figures seem to move in light and air, and in this respect he resembles greatly his fellow-worker De Hooch, who entered the guild of St Luke only two years later than Van der Meer. It is curious to read that, at one of the auctions in Amsterdam about the middle of last century, a De Hooch is praised as being "nearly equal to the famous Van der Meer of Delft." So nearly are they allied that the best judges are divided in opinion whether the Dutch Family ("La Promenade") of the academy of Vienna should be attributed to our painter or to De Hooch. Doubtless many of Van der Meer's works have yet to be restored to their proper author; but, as he is now in vogue, much care will have to be used in judging. This is specially true in regard to the landscapes and "still life" subjects which are attributed to him. The task is made more difficult by the diversity of style of this "Protean painter," as he is called by Dr Waagen, or, as Bürger names him, "the Sphinx of Delft."

MEERANE, a rapidly increasing industrial town in south-eastern Saxony, lies in the district of Zwickau, about 37 miles to the south of Leipsic. It contains an old church, a "Realschule," and a technical school for weavers. The leading industry is the weaving of woollen and half-woollen cloth, employing 3000 power-looms and 15,000 hand-looms, and producing goods of the annual value of upwards of £200,000. A large proportion of the cloth is exported to America and Japan. Meerane also possesses several important dye-works, besides smaller industrial establishments of various kinds. The population in 1880 was 22,293.

MEERSCHAUM. This German name is applied to a certain mineral, in consequence of its lightness, softness, and white colour, which suggest a resemblance to "sea foam." In like manner it is called in French *écume de mer*. By the German mineralogist Glocker it was termed *sepiolite*, in allusion to its resemblance to the so-called bone of the sepia or cuttle-fish. Possibly the fact that pieces of meerschaum, washed out of their matrix, are occasionally found floating on the Black Sea, may have led to the association of the mineral with marine products. Meerschaum is an opaque earthy mineral, of white, greyish, or yellowish colour, compact in texture, and breaking with a conchoidal or fine earthy fracture; it adheres to the tongue, and is so soft as to be scratched by the nail, its degree of hardness being about 2 or 2·5. Its specific gravity varies from 0·988 to 1·279; hence it floats in sea-water until saturated. Meerschaum is a hydrated silicate of magnesium, represented by the formula $Mg_2Si_3O_8 + nH_2O$. The value of $n$, according to some analyses, is 2. Most of our meerschaum comes from Asia Minor, especially from the plains of Eski-shehr, where it occurs in nodular masses, of variable size and irregular shape, distributed through the alluvial deposits of the plain, which are systematically worked for its extraction by means of pits and galleries. The mineral is associated with magnesite, or carbonate of magnesium, and has probably been derived from the neighbouring mountains, where a similar carbonate is found in connexion with serpentine. Meerschaum is found also, though less abundantly, in Greece and in some of the Grecian islands; at Hrubschitz in Moravia, where it occurs in a serpentinous matrix; and in Morocco, where it is used, when soft and fresh, as a substitute for soap; while a coarse variety is found at Vallecas near Madrid, and is employed as a building stone. Meerschaum also occurs in South Carolina.

By far the greatest quantity of meerschaum is used in the manufacture of tobacco-pipes, a purpose for which it is well fitted by its porosity. The nodular masses are first roughly scraped in order to remove the red earthy matrix; they are then dried, scraped again, and finally polished with wax. In this state the rudely-shaped nodular pieces are sent from the East principally to Vienna and to various parts of Germany. The pipe-bowls, after having been turned and carved, are rubbed with glass-paper and Dutch rushes; they are next boiled in wax, spermaceti, or stearine, and afterwards subjected to careful polishing with bone-ash, chalk, &c.

An imitation of meerschaum for common pipes is made of hardened plaster of Paris, treated with paraffin, and coloured by gamboge and dragon's blood. A peculiar preparation, into which potato largely enters, is said to have been successfully employed in France as a substitute for meerschaum.

MEERUT, or MÍRATH, a district in the division[1] of

[1] The division lies between 27° 38′ and 30° 57′ N. lat., and between 77° 7′ and 78° 42′ E. long., and comprises the six districts of Dehra Dun, Saháranpur, Muzaffarnagar, Meerut, Bulandshahr, and Alígarh. The area in 1878 was 11,138 square miles, and the population in 1872 4,977,173.

Meerut and the lieutenant-governorship of the North-Western Provinces, India, lying between 28° 28′ and 29° 18′ N. lat., and 77° 10′ and 78° 14′ E. long., is bounded on the N. by Muzaffarnagar district, on the E. by the Ganges, on the S. by Bulandshahr district, and on the W. by the Jumna. The area in 1881 was given as 2361 square miles. Meerut forms a portion of the long and narrow plain lying between the Ganges and the Jumna, with a very gentle slope from north to south. Though well wooded in places and abundantly supplied with mango groves, it has but few patches of jungle or waste land to break the general expanse of cultivated soil. Sandy ridges run along the low watersheds which separate the minor channels, but with this exception the whole district is one continuous expanse of careful and prosperous tillage. Its fertility is largely due to the system of irrigation canals, which intersect it in every direction. The eastern Jumna canal runs through the whole length of the district, and supplies the rich tract between the Jumna and the Hindan with a network of distributary streams. The main branch of the Ganges canal passes across the centre of the plateau in a sweeping curve, and waters the midland tract. The Anúpshahr branch supplies irrigation to the Ganges slope. Besides these natural and artificial channels, the country is everywhere cut up by small water-courses. The Burh Gangá, or ancient bed of the Ganges, lies at some distance from the modern stream; and on its bank stood the abandoned city of Hastinapur, the legendary capital of the Pandavas at the period of the *Mahábhárata*, said to have been deserted many centuries before the Christian era, owing to the encroachments of the river.

The census of 1872 returned the population of the district at 1,276,104, the Hindus numbering 991,226. Among the higher castes Bráhmans muster strong (109,804). The Rájputs (both Hindus and Mohammedans) number 55,083, and enjoy great social distinction as landholders; the Baniás, or traders (66,942), also now hold considerable landed property. The great cultivating castes are the Chamárs (197,273) and Játs (145,514). The Gujars (60,350) are a pastoral tribe, with an ancient character for plunder and cattle-lifting, which is now passing away. The Mohammedans (281,857) are for the most part the descendants of converted Hindus. The Christian population consists of 2149 Europeans, 142 Eurasians, and 730 natives. Fifteen towns in the district contain a population exceeding 5000; namely, Meerut, 81,386; Hápur, 14,544; Sardhána, 12,466; Garhmukhtesar, 7962; Bágpat, 7367; Ghaziábád, 7365; Shahdara, 7257; Baro, 7056; Mawána, 6864; Pilkhuá, 6239; Khekara, 6045; Tikri, 5698; Kirthal, 5651; Dasna, 5605; Chaprauli, 5594.

Meerut is one of the most flourishing and best tilled districts of the Doáb. Out of a total area of 1,505,824 acres, as many as 1,048,221 were under cultivation in 1881, 281,095 acres being irrigated by Government works, and 303,526 by private individuals. The grazing lands comprehended 242,091 acres, and the waste 185,400. The condition both of agricultural labourers and of artisans and workmen in the towns has considerably improved of late years. About one-half the soil is cultivated by the proprietors themselves, the remainder being about equally divided between tenants with occupancy rights and tenants-at-will. Rents are paid in money, and range from 18s. 10d. per acre for the best canal-watered lands down to 2s. 5½d. per acre for "dry" unirrigated soils. The chief exports of the district are grain, cotton, and indigo; and the principal imports are Manchester goods, English hardware, tobacco, drugs, and spices. The chief commercial centres are Meerut, Ghaziábád, and Bágpat. Besides the great waterways of the Jumna and Ganges, and the navigable canals, communication is afforded by the East Indian and the Punjab and Delhi Railways; also by 1505 miles of made roads. In 1876 the district was in the administrative charge of four covenanted civilians, and contained seventeen magisterial and fifteen civil courts. The gross revenue in 1881 was £248,754, of which £203,977 was derived from the land-tax; the cost of officials and police was £27,520. In 1881 there were 214 schools, attended by 6677 pupils. The comparatively high latitude and elevated position of Meerut make it one of the healthiest districts in the plains of India. The average temperature varies from 57° Fahr. in January to 87° in June. The rainfall is small, less than 30 inches annually. The only endemic disease in the district is malarial fever; but small-pox and cholera occasionally visit it as epidemics.

The authentic history of the district commences with the Moslem invasions. Until the 11th century it is probable that Meerut was mainly in the hands of predatory native tribes, such as the Játs and Dors. The first undoubted Mohammedan invasion was that of Kutab-ud-dín in 1191, when Meerut town was taken, and all the Hindu temples turned into mosques. In 1398 Timúr swooped down upon the district, captured the fort of Loni after a desperate resistance, and put all his Hindu prisoners to death. He then proceeded to Delhi, and after his memorable sack of that city, returned to Meerut, captured the town, razed all the fortifications and houses of the Hindus, and put the male inhabitants to the sword. The firm establishment of the great Mughal dynasty in the 16th century, under Bábar and his successors, gave Meerut a period of internal tranquillity and royal favour. After the death of Aurangzeb, however, it was exposed to alternate Sikh and Mahratṭá invasions. From 1707 till 1775 the country was the scene of one perpetual strife, and was only rescued from anarchy by the exertions of the military adventurer Walter Reinhardt, afterwards the husband of the celebrated Begám Samru, who established himself at Sardhána in the north, and ruled a large estate. The southern tract, however, remained in its anarchic condition under Mahrattá exactions until the fall of Delhi in 1803, when the whole of the country between the Jumna and the Ganges was ceded by Sindhia to the British. It was formed into a separate district in 1818. In the British period it has become memorable as being the place where the first outbreak of the great mutiny of 1857 took place

MEERUT, a city, and cantonment in the above district, is situated about half way between the Ganges and the Jumna, in 29° 0′ 41″ N. lat. and 77° 45′ 3″ E. long. The city proper lies south of the cantonments, and although a very ancient town, dating as far back as the days of the Buddhist emperor Asoka (*circ.* 250 B.C.), Meerut owes its modern importance to its selection by the British Government as the site of a great military station. In 1805 it is mentioned as "a ruined depopulated town." The cantonment was established in 1806, and the population rose rapidly to 29,014 in 1847, and 82,035 in 1853. In 1872 the census returned the population (exclusive of the military) at 81,386, viz., Hindus, 47,606; Mohammedans, 33,532; Christians, 248. The slight decline of population between 1853 and 1872 may probably be attributed to the mutiny of 1857. Most of the streets have a poor appearance, owing to the hasty manner in which they were erected. The cantonment, a little to the north of the city, forms the headquarters of a military division. The principal building is the Meerut church with its handsome tall spire. There are also a Roman Catholic church, mission chapel, asylum for the relief of Europeans and Christians, and a club. The Mall is one of the finest drives in India.

MEGALOPOLIS, a city of southern Arcadia, situated in a plain about 20 miles south-west of Tegea, on both banks of the Helisson, about 2½ miles above its junction with the Alpheus. Like Messene, it owed its origin to Epaminondas, and was founded in 370 B.C., the year after the battle of Leuctra, as a bulwark for the southern Arcadians against Sparta, and as the seat of the Arcadian federal diet, which consisted of ten thousand men. The builders of the city were protected by a Theban force, and directed by ten native œcists, who likewise attended to the peopling of the new city, which apparently drew inhabitants from all parts of Arcadia, but more especially from the neighbouring districts of Mænalia and Parrhasia. Forty townships are mentioned by Pausanias (viii. 27, 3–5) as having been incorporated in it. It was fifty stadia in circumference, and was surrounded with strong walls. Its territory was the largest in Arcadia, extending northward 24 miles. The city was built on a magnificent scale, and adorned with many handsome buildings, both public and private. Its temples contained many ancient statues brought from the towns incorporated in it. On the north side of the Helisson, which divided it into two nearly equal parts, was the agora with four porticos, the gymnasium, a sacred grove, temples to the Lycæan Zeus, Pan Oinoeis, Rhea, Tyche, the great goddesses (Demeter and Coré), Zeus Philios (with a statue by Polycletus), Aphro-

dite, Core, Athena Polias, and Hera Teleia. Among the numerous statues which stood in the open air the finest was that of Apollo Epicurius, 12 feet high, brought from the beautiful temple of Bassæ, which was built by Ictinus, and is still in great part standing. On the south side of the river were the theatre, the largest in Greece, the Thersilion or hall for the assembly of the Arcadian diet, a house built for Alexander the Great, with a statue of Zeus Ammon, the stadium, temples to the Muses, Apollo, and Hermes, to Aphrodite, to Ares, to Dionysus, to Hercules and Hermes, to Artemis Agrotera, to Asclepius and Hygiea, to the son of Asclepius, and to Apollo. Of all these buildings, with the exception of the theatre, hardly a trace remains above ground. The ruins of Megalopolis are near Sinanou.

The foundations of Megalopolis were hardly laid when Agesilaus undertook an expedition in the hope of breaking up the union of which it was the visible sign and capital. He accomplished nothing, and had hardly reached home when the Thebans and their allies under Epaminondas and Pelopidas entered the Peloponnesus and marched through Laconia almost unopposed. After the departure of Epaminondas, Lycomedes of Mantinea succeeded in drawing the Arcadian federation away from its alliance with Thebes, in consequence of which it had to make common cause with Athens. An attempt on the part of the federation to use the treasures of the temple of Zeus at Olympia led to internal dissensions, so that in the battle of Mantinea (362) one half of the Arcadians fought on the side of the Spartans, the other on that of the Thebans. After this battle many of the inhabitants of Megalopolis sought to return to their former homes, and it was only by the assistance of three thousand Thebans under Pammenes that the authorities were able to prevent them from doing so. In the year 352, when Thebes had her hands full with the so-called Sacred War, the Spartans made an attempt to reduce Megalopolis; but the Thebans promptly sent assistance, and the city was rescued. Not sure of this assistance, the Megalopolitans had appealed to Athens, an appeal which gave occasion to Demosthenes's oration Περὶ Μεγαλοπολιτῶν. The Spartans were now obliged to conclude peace with Megalopolis and acknowledge her autonomy. Nevertheless their feeling of hostility did not cease, and Megalopolis consequently entered into friendly relations with Philip of Macedon. Twenty years later, when the Spartans and their allies rebelled against the power of Macedon, Megalopolis remained firm in its allegiance, and was subjected to a siege of considerable duration. After the death of Alexander, Megalopolis was governed by native tyrants. In the war between Cassander and Polysperchon it took part with the former, and was, in consequence, besieged by the latter. On this occasion it was able to send into the field an army of fifteen thousand. In 234 B.C. Lydiades, the last tyrant of Megalopolis, voluntarily resigned his power, and the city joined the Achæan league. In consequence of this it was once more exposed to the bitter hatred of Sparta. In 222 Cleomenes took and plundered it, and killed or dispersed its inhabitants, but in the year following it was restored, and its inhabitants reinstated by Philopœmen, a native of the city. At this time the circuit of its walls always too great, seems to have been contracted. At all events it never again attained political importance, and gradually sank into insignificance. The only great men whom it produced were Philopœmen and Polybius the historian. Lycortas, the father of the latter, may be accounted a third. In the time of Pausanias the city was mostly in ruins.

MEGALOSAURUS. See Reptiles.

MEGAPODE, the name given generally to a small but remarkable Family of birds, highly characteristic of some parts of the Australian Region, to which it is almost peculiar. The *Megapodiidæ* with the *Cracidæ* form that division of the Order *Gallinæ* named by Professor Huxley *Peristeropodes* (*Proc. Zool. Society*, 1868, p. 296), and morphologically seem to be the lowest of the Order, with which apparent fact may perhaps be correlated their singular habit of leaving their eggs to be hatched without incubation, burying them in the ground (as many Reptiles do) or heaping over them a mound of earth, leaves, and rotten wood. This habit attracted attention more than three hundred years ago,[1] but the accounts given of it by various travellers were generally discredited by naturalists,[2] and as examples of the birds, probably from their unattractive plumage, appear not to have been brought to Europe, no one of them was seen by any ornithologist or scientifically described until near the end of the first quarter of the present century. The first member of the Family to receive authoritative recognition was one of the largest, inhabiting the continent of Australia, where it is known as the Brush-Turkey, and was originally described by Latham in 1821 under the name of the New-Holland Vulture, a misleading designation which he subsequently tried to correct on perceiving its Galline character. It is the *Talegallus lathami* of modern ornithologists, and is nearly the size of a hen Turkey. Six smaller species of the same genus have since been described, all from New Guinea or the neighbouring islands, but two of them, *T. pyrrhopygius* and *T. bruyni*, have been separated to form a group *Æpypodius*. The Australian bird is of a sooty-brown colour, relieved beneath by the lighter edging of some of the feathers, but the head and neck are nearly bare, beset with fine bristles, the skin being of a deep pinkish-red, passing above the breast into a large wattle of bright yellow. The tail is commonly carried upright and partly folded, something like that of a domestic Fowl.

The next form of which we may speak is another inhabitant of Australia, commonly known in England as the Mallee-bird, but to the colonists as the "Native Pheasant"—the *Lipoa ocellata*, described by Gould in the zoological *Proceedings* for 1840 (p. 126), which has much shorter tarsi and toes, the head entirely clothed, and the tail expanded. Its plumage presents a pleasing combination of greys and browns of various tints, interspersed with black, white, and buff, the wing-coverts and feathers

[1] Antonio Pigafetta, one of the survivors of Magellan's glorious but disastrous voyage, records in his journal, under date of April 1521, among the peculiarities of the Philippine Islands, then first discovered by Europeans, the existence of a bird there, about the size of a Fowl, which laid its eggs, as big as a Duck's, in the sand, and left them to be hatched by the heat of the sun (*Premier Voyage autour du Monde*, ed. Amoretti, Paris, A.R. ix. p. 88). More than a hundred years later the Jesuit Nieremberg, in his *Historia Naturæ*, published at Antwerp in 1635, described (p. 207) a bird called "Daie," and by the natives named "Tapun," not larger than a Dove, which, with its tail (!) and feet, excavated a nest in sandy places and laid therein eggs bigger than those of a Goose. The publication at Rome in 1651 of Hernandez's *Hist. Avium Novæ Hispaniæ* shews that his papers must have been accessible to Nieremberg, who took from them the passage just mentioned, but, as not unusual with him, misprinted the names which stand in Hernandez's work (p. 56, cap. 220) "Daic" and "Tapum" respectively, and omitted his predecessor's important addition "Viuit in Philippicis." Not long after, the Dominican Navarrete, a missionary to China, made a considerable stay in the Philippines, and returning to Europe in 1673 wrote an account of the Chinese empire, of which Churchill (*Collection of Voyages and Travels*, vol. i.) gave an English translation in 1704. It is therein stated (p. 45) that in many of the islands of the Malay Archipelago "there is a very singular bird call'd *Tabon*," and that "What I and many more admire is, that it being no bigger in Body than an ordinary Chicken, tho' long legg'd, yet it lays an Egg larger than a Gooses, so that the Egg is bigger than the bird itself. . . . In order to lay its Eggs, it digs in the Sand above a yard in depth; after laying, it fills up the hole and makes it even with the rest; there the Eggs hatch with the heat of the Sun and Sand." He adds further information which need not be quoted here. Gemelli Careri, who travelled from 1663 to 1699, and in the latter year published an account of his voyage round the world, gives similar evidence respecting this remarkable bird, which he calls "Tavon," in the Philippine Islands (*Voy. du tour du Monde*, ed. Paris, 1727, v. pp. 157, 158). The Megapode of Luzon is fairly described by Camel or Camelli in his observations on the Birds of the Philippines communicated by Petiver to the Royal Society in 1703 (*Phil. Trans.*, xxiii. p. 1398). In 1726 Valentyn published his elaborate work on the East Indies, wherein (deel iii. bk. v. p. 320) he very correctly describes the Megapode of Amboina under the name of "Maleloe," and also a larger kind found in Celebes, so as to shew he had in the course of his long residence in the Dutch settlements become personally acquainted with both.

[2] Thus Willughby (*Ornithologia*, p. 297), or Ray for him, who had, however, only Nieremberg's evidence to cite, and they can scarcely be blamed for their hesitation, considering the number of other marvels narrated by the same worthy father. Buffon also (*Oiseaux*, ix. p. 436) was just as sceptical in regard to the relation of Careri.

of the back bearing each near the tip an oval or subcircular patch, whence the trivial scientific name of the bird is given, while a stripe of black feathers with a median line of white extends down the front of the throat, from the chin to the breast. There is but one species of this genus known, as is also the case with the next to be mentioned, which is a singular bird long known to inhabit Celebes, but not fully described until 1846,[1] when it received from Salomon Müller (*Arch. f. Naturgeschichte*, xii. pt. 1, p. 116) the name of *Macrocephalon maleo*, but, being shortly afterwards figured by Gray and Mitchell (*Gen. Birds*, iii. pl. 123) under the generic term of *Megacephalon*, has since commonly borne the latter appellation. This is a very remarkable form, bearing a helmet-like protuberance on the back of its head, all of which as well as the neck is bare and of a bright red colour; the plumage of the body is glossy black above, and beneath roseate-white.

Of the Megapodes proper, constituting the genus *Megapodius*, many species have been described, but authorities are greatly at variance as to the validity of several, and here it would be impossible to name all that have been supposed to exist. Some are only known from very young examples—mere chickens; and some have even been described from their eggs alone. In 1870 Mr G. R. Gray enumerated twenty species, of which sixteen were represented in the British Museum, and several have been described since; but ten years later Professor Schlegel recognized only seventeen species, of which examples of twelve were contained in the Leyden Museum (*Mus. des Pays-Bas*, viii., Monogr. 41, pp. 56–86), while M. Oustalet, in his elaborate monograph of the Family (*Ann. Sc. Nat., Zoologie*, ser. 6, vols. x. and xi.), admits nineteen species. The birds of this genus range from the Samoa Islands in the east, through the Tonga group, to the New Hebrides, the northern part of Australia, New Guinea and its neighbouring islands, Celebes, the Pelew Islands, and the Ladrones, and have also outliers in detached portions of the Indian Region, as the Philippines (where indeed they were first discovered by Europeans), Labuan, and even the Nicobars—though none are known from the intervening islands of Borneo, Java, or Sumatra. Within what may be deemed their proper area they are found, says Mr Wallace (*Geogr. Distr. Animals*, ii. p. 341) "on the smallest islands and sand-banks, and can evidently pass over a few miles of sea with ease." Indeed proof of their roaming disposition is afforded by the fact that the bird described by Lesson (*Voy. Coquille: Zoologie*, p. 703) as *Alecthelia urvillii*, but now considered to be the young of *Megapodius freycineti*, flew on board his ship when more than 2 miles from the nearest land (Guebé), in an exhausted state, it is true, but that may be attributed to its extreme youth. The species of *Megapodius* are about the size of small Fowls, the head generally crested, the tail very short, the feet enormously large, and, with the exception of *M. wallacii* (*Proc. Zool. Society*, 1860, *Aves*, pl. 171), from the Moluccas, all have a sombre plumage.

The extraordinary habit possessed by the Megapodes generally of relieving themselves of the duty of incubation, as before mentioned,—a habit which originally attracted the attention of travellers, whose stories were on that very account discredited,—as well as the highly developed condition of the young at birth, has been so fully described by Gould (*Handb. B. Australia*, ii. pp. 152–175), G. R. Gray (*Proc. Zool. Society*, 1861, pp. 292–296), and Mr Wallace (*Malay Archipelago*, i. pp. 415–419; ii. pp. 147–149), and so often repeated by other writers, as to be very commonly known, and here there seems no necessity to enter into further details concerning it. (A. N.)

MEGARA was the name of two Greek towns, one in Sicily, which has been already described under Hybla, the other on the road from Attica to Corinth. The country which belonged to the city was called Μεγαρίς or ἡ Μεγαρική; it occupied the broader part of the isthmus between Attica, Bœotia, Corinth, and the two gulfs, and its whole area is estimated by Clinton at 143 square miles. The range of Mount Geraneia extends across the country from east to west, forming a barrier between continental Greece and the Peloponnesus. The shortest road across this range passes along the eastern side of the mountains, and the most difficult part is the celebrated Scironian rocks, the mythic home of the robber Sciron. The only plain in the rugged little country was the White Plain, in which was situated the only important town, Megara. The town was one of the most important commercial and colonizing centres of Greece in early times, and there is no doubt that its trade, like that of Corinth, owed its origin to the Phœnicians, who found its situation on the isthmus convenient. It became a Dorian city when that tribe conquered the Peloponnesus. Like many other cities of Greece, Megara was formed out of five villages, which were united on one political foundation; and this event must have taken place not later than the middle of the 8th century. From this time for two centuries Megara was among the most powerful cities of Greece. Though it had a harbour called Pegæ on the Corinthian Gulf, and founded a Sicilian colony, Megara Hyblæa, in 728 B.C., yet it did not long compete with Corinth and Coreyra for the western trade. Nisæa on the Saronic Gulf was a better harbour, and gave the Megarians a stronger footing on the eastern seas. In order to keep their hold on the Black Sea traffic, they founded numerous trading stations alongside of their chief rivals, the people of Miletus: Chalcedon and Byzantium on the Bosphorus, and Astacus and Heraclea in Bithynia were colonies of Megara. Wealth and culture increased in the city; the country festivals were celebrated in a more elaborate and orderly manner, and Susarion of Tripodiscus first gave literary form to Grecian comedy, which was soon transferred to Attica.

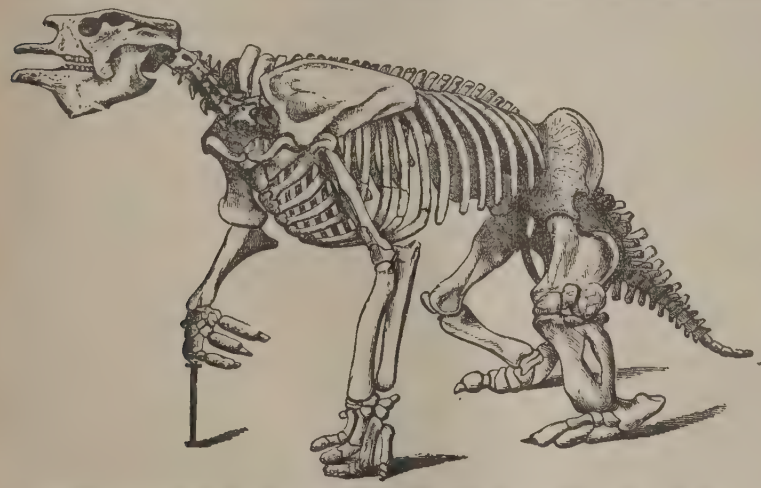
The situation of Megaris on the isthmus gave it great political power, inasmuch as it commanded all the roads from the Peloponnesus into continental Greece; and so long as the people continued united under an orderly government they maintained their high position. But the development of education prompted the lower classes to demand from the nobles an equal share in the government, and Megara did not, like Athens and Sparta, produce a constitution which could reconcile the contending parties. A tyrant Theagenes raised himself to supreme power as the leader of the popular party; he made an aqueduct for the city, and appears to have maintained its power and splendour. But he was expelled by the nobles about 600 B.C., and for many years Megara was the scene of continual struggles. The poor, who were indebted to the rich, refused to pay what they counted exorbitant interest, and plundered the houses of the nobles. A vivid picture of the state of the city in the 6th century B.C. is preserved in the writings of the poet Theognis, who belonged to the aristocratic party. Meanwhile Athens was rising to power, and maintained a long war with Megara for the island of Salamis. The Megarians gradually lost strength, and finally Solon wrested the island from them for ever. They sent three thousand troops to fight at Platæa. In the wars between Athens and Sparta they were impelled by jealousy of their neighbours of Corinth to join the Athenian alliance, 455–45; but they soon found that they were only the subjects of Athens, and finally

[1] As we have seen, it was mentioned in 1726 by Valentyn, and a young example was in 1830 described and figured by Quoy and Gaimard (*Voy. de l'Astrolabe: Oiseaux*, p. 239, pl. 25) as the *Megapodius rubripes* of Temminck, a wholly different bird.

enrolled themselves among the allies of Sparta. They suffered terribly during the Peloponnesian War: Athenian ships blockaded their harbours and Athenian armies ravaged their land once or twice every year. The long famine in the city is referred to by Aristophanes in the *Acharnians*. The city maintained a flourishing existence throughout the Greek and Roman periods, but played a very subordinate part in history. In the unsettled time when the Roman empire had decayed, it was often plundered by pirates.

As regards literature, Megara's chief distinction, besides the poems of Theognis and the comedy of Susarion, was the school of philosophy founded there by Euclid, a disciple of Socrates. The coinage of the city is a very confused and difficult subject; no very early coins can be with certainty attributed to it. The usual types are Apolline. The topography is described by Pausanias, bk. i. Megara is about four hours' carriage-drive from Athens.

MEGATHERIUM is the name given by Cuvier to a large extinct animal belonging to the order *Edentata* (see MAMMALIA, p. 384). A nearly complete skeleton, found on the banks of the river Luxan, near Buenos Ayres, and sent in 1789 to the Royal Museum at Madrid, long



Skeleton of the Megatherium, from the specimen in the Museum of the Royal College of Surgeons of England. $\times \frac{1}{15}$.

remained the principal if not the only source of information with regard to the species to which it belonged, and furnished the materials for many descriptions, notably that of Cuvier, who determined its affinities with the Sloths.[1] In 1832 an important collection of bones of the Megatherium were discovered near the Rio Salado, and were secured for the museum of the College of Surgeons of England, and these, with another collection found at Luxan in 1837, and now in the British Museum, supplied the materials for the complete description of the skeleton published by Professor Owen in 1861. Other skeletons have subsequently been received by several of the Continental museums, as Milan and Paris, and, consequently, our knowledge of the organization of the Megatherium, so far as it can be deduced from the bones and teeth, is as complete as that of any other animal, recent or extinct.

The remains hitherto spoken of are all referred to one species, *Megatherium americanum* of Blumenbach, *M. cuvieri* of Desmarest, and are all from the newest or post-Tertiary geological formations of the Argentine Republic and Paraguay, or the lands forming the basin of the Rio de la Plata. Dr Leidy has described, from similar formations in Georgia and South Carolina, bones of a closely allied species, about one-fourth smaller, which he has named *M. mirabile*. A third species, *M. laurillardi* of Lund, is founded upon remains found in Brazil.

The following description will apply especially to the best-known South American form, *Megatherium americanum*. In size it exceeded any existing land animal except the elephant, to which it was inferior only in consequence of the comparative shortness of its limbs, for in length and bulk of body it was its equal, if not superior. The full length of a mounted skeleton from the fore part of the head to the end of the tail is 18 feet, of which the tail occupies 5 feet. The head, which is small for the size of the animal, presents a general resemblance to that of the Sloth; the anterior part of the mouth is, however, more elongated, and the malar bone, though branched posteriorly in the same way as that of the Sloth, meets the zygomatic process of the squamosal, completing the arch. The lower jaw has the middle part of its horizontal ramus curiously deepened, so as to admit of implantation of the very long-rooted teeth. In number the teeth exactly resemble those of the Sloths, being five above and four below on each side, and they are limited to the lateral parts of the mouth, front teeth being entirely wanting. They resemble those of the Sloths also in their persistent growth, and in their composition of three tissues — vaso-dentine, true dentine, and cement; but they are of prismatic or quadrate form, and the constituent materials of different densities are so arranged that, as they wear, two transverse ridges of hard dentine remain at a greater elevation than the rest of the tooth, producing a very efficient triturating apparatus (see figs. 35 and 36, article MAMMALIA, p. 385). The vertebral column consists of seven cervical, sixteen dorsal, three lumbar, five sacral, and eighteen caudal vertebræ. The spinous processes are much better developed than in the Sloths, and are all directed backwards, there being no reversing of the inclination near the posterior end of the dorsal series, as in most active-bodied mammals. In the lumbar region, the accessory zygapophyses, rudimentary in Sloths, are fully developed, as in the Anteaters.

The tail is large, and its basal vertebræ have strong lateral and spinous processes and chevron bones, indicating great muscular development. The scapula resembles that of the Sloths in the union of the acromion with the coracoid, and in the bridging over of the supra-scapular notch. The clavicle is complete and very large much resembling that of man on a large scale. The fore limbs are longer than the hind limbs. The radius and ulna are both well-developed, and have a considerable amount of freedom of movement. The hand is singularly modified. The first digit is represented only by a rudimentary metacarpal, but the next three are large, and terminate in phalanges

[1] An excellent figure of this skeleton, which unfortunately was incorrectly articulated, and wanted the greater part of the tail, was published by Pander and D'Alton in 1821, and has been frequently reproduced in subsequent works.

adapted for the support of immense claws, the middle one being especially large. The outer or fifth digit has no claw, and it may be considered as certain that the weight of the foot was, in standing and walking, chiefly thrown upon this, and that it was protected by a callous pad below as in the existing great Anteater, while the other toes were curved inwards towards the palm, only coming in contact with the ground by their outer surfaces. The mechanical arrangements by which the weight of the body was thrown entirely upon the outer side of the foot are very curious, and are fully described in Professor Owen's memoir. The pelvis is remarkably wide, even more so than that of the Elephant, but it is formed on the same principle as in the Sloths. The femur is extremely broad and flattened; the tibia and fibula are short and strong, and united together at each end. The hind foot, contrary to the usual rule in the *Edentata*, is even more singularly modified than the hand. The ankle-joint is formed upon a peculiar plan, quite unlike that of the Sloths, or of any other mammal, except the Megatherium's nearest allies. The calcaneum projects nearly as far backwards as the fore part of the foot does forwards. There is no trace of great toe or hallux, or of its corresponding cuneiform bone. The second toe is rudimentary. The third has an enormous ungual phalanx, which, like those of the hand, is remarkable for the immense development of the bony sheath which is reflected from its proximal end around the base of the claw. The two outer toes have large and very peculiarly-shaped metatarsals, but only small phalanges, and no claws. The creature probably walked upon the outer edge of the sole, so that the great falcate claw of the third toe did not come into contact with the ground, and so was kept in a state of sharpness ready for use. The foot was therefore formed upon quite a different principle from that of the Anteaters or Sloths, though somewhat like the latter in having two of the toes aborted.

Taking all the various points of its structure together, they clearly indicate affinities both with the existing Sloths and with the Anteaters, the skull and teeth more resembling those of the former, and the vertebral column and limbs the latter It is also not difficult to infer the food and habits of this enormous creature. That it was a leaf-eater there can be little doubt, but the greater size and more complex structure of its teeth might have enabled it to crush the smaller branches as well as the leaves and succulent shoots which form the food of the existing Sloths. It is, however, very improbable that it climbed into the branches of the trees like its diminutive congeners, but it is far more likely that it obtained its subsistence by tearing them down with the great hook-like claws of its powerful prehensile fore limbs, being easily enabled to reach them by raising itself up upon the massive tripod formed by the two hind feet, firmly fixed to the ground by the one huge falcate claw, and the stout, muscular tail. The whole conformation of the hinder part of the animal is strongly suggestive of such an action. There can also be little doubt but that all its movements were as slow and deliberate as those of its modern representatives.

An idea at one time prevailed that the Megatherium was covered externally with a coat of bony armour like that of the Armadillos, but this originated in dermal plates belonging to the Glyptodon, a totally distinct animal, having been accidentally associated with bones of the Megatherium. Similar plates, on a smaller scale, have indeed been found in connexion with the skeleton of both Mylodon and Scelidotherium, animals of the same family, but never yet with the Megatherium, which we may therefore imagine with a covering of coarse hair like that of its nearest living allies, the Sloths and Anteaters.

MEGHNÁ, a river of India, forming, in the lower part of its course, the great estuary of the Bengal delta, which conveys to the sea the main body of the waters of the Ganges and the Brahmaputra, which unite at Goalánda in Faridpur district. The united waters thence roll south—a mighty river of great depth and turbidness, sometimes split up into half a dozen channels by sand-banks of its own formation, sometimes spreading out into a widespread sheet of water which the eye cannot see across. The river enters the sea by four principal mouths, enclosing the three large islands of Dakshin Sháhbazpur, Hatia, and Sandwíp. It is navigable by native boats of the largest burden, and also by river steamers, all the year through; but the navigation is difficult, and sometimes dangerous, on account of shifting sand-banks and "snags," and boisterous weather when the monsoon is blowing. The most favourable season for navigation is between November and February. Alluvion and diluvion are constantly taking place, especially along the seaboard, and in Noákhálí district the land is said to have advanced seawards 4 miles in twenty-three years; while the islands fringing the mouth are annually being cut away and redeposited in fresh shapes.

The tidal phenomena of the Meghná surpass those of any other Indian river. The regular rise of the tide is from 10 to 18 feet, and at springs the sea rushes up in a single wave, known as the "bore,"—on the Meghná a justly dreaded danger to boatmen. It is greatest at the time of the biennial equinoxes, when navigation is sometimes impeded for days together. The tidal wave is suddenly beheld advancing like a wall topped with foam of the height of nearly 20 feet, and at the rate of 15 miles an hour; in a few minutes all is over, and the river has changed from ebb to flood tide. A still greater danger is the "storm wave," which occasionally sweeps up the Meghná in the shape of cyclones. The latest and most destructive of these disasters were those of May 1867 and October 1876, when the whole islands and sea-face of the mainland were entirely submerged. In the latter calamity it has been officially estimated that about 19 per cent. of the population in the mainland portion of Noákhálí, and in the islands of Sandwíp and Hatia, were drowned, and that a like proportion subsequently died of cholera and other diseases caused by the results of the storm.

MEHÁDIA, a market-town in the county of Szörény, Hungary, is situated on the Bella-Reka, or Bereka, 13½ miles north of Orsova, in 44° 55′ N. lat., 22° 22′ E. long. The town is small but thriving, and contains Greek Orthodox and Roman Catholic churches, the ruins of a castle, and some interesting Roman antiquities. Mehádia is, however, chiefly of importance as the station for the Hercules Baths, distant about 3 miles east from the town, and situated in a narrow pass in the romantic valley of the Cserna. Of the twenty-two hot springs of Mehádia, nine are now in use, the most powerful one being the Hercules, which yields about 5000 cubic feet of water per hour. The springs are all strongly impregnated with salts of sulphur, iodine, bromine, and chlorine, and their average temperature is 70° to 145° Fahr. They are much used for chronic rheumatism, gout, and cutaneous eruptions, and during the season, which usually lasts from the middle of

May to the end of September, are resorted to by over a thousand visitors. The town of Mehádia has about 2200 inhabitants, principally Roumanians and Germans.

Already in the times of the Romans famous for their healing efficacy, the *Thermæ Herculis* (*Fontes Herculis, Aquæ Herculis*) were the resort of emperors, generals, and senators, whose sojourn there is attested by various inscriptions and relics. The town is the site of the ancient Roman colony of *Ad Mediam*, near which the Roman road from the Danube to Dacia passed in its course through the valley of the Cserna. Subsequent to the destruction of the Roman empire the baths fell into disuse until 1735; great improvements have been effected in them during the present century, and recently a spacious kursaal has been built at the expense of the Hungarian Government. The fortress of Mehádia was often stormed during the wars with the Turks, and notably in 1716, 1738, and 1789.

MEHEMET ALI or Mohammed 'Alí. See Egypt, vol. vii. p. 760 *sq.*

MÉHUL, Étienne Henri (1763–1817), one of the most remarkable composers of France, was born at Givet, in Ardennes, on the 24th of June 1763. His father being too poor to give him a regular musical education, his first ideas of art were derived from a poor blind organist of Givet; yet such was his aptitude that, when ten years old, he was appointed organist of the convent of the Récollets. In 1775 an able German musician and organist, Wilhelm Hauser, was engaged for the monastery of Lavaldieu, a few miles from Givet, and Méhul became his occasional pupil. In his sixteenth year he was taken to Paris by a military officer, and placed himself under Edelmann, a good musician and harpsichord player. His first attempts at instrumental composition in 1781 did not succeed, and he therefore turned his attention to sacred and dramatic music. The great composer Gluck received him kindly, and gave him advice in his studies. After various delays and disappointments during his efforts for six years to obtain, at the Grand Opera, a representation of his *Cora et Alonzo*, he offered to the Opéra Comique his *Euphrosine et Coradin*, which, being accepted and performed in 1790, at once fixed his reputation. The critics acknowledged in it great energy of dramatic expression, and much brilliant instrumentation, but objected to a general want of graceful melody,—a strange complaint, since his style is far more refined than that of either Hérold or Auber. His opera of *Stratonice* had great success. After several other operas which did not succeed, his *Adrien* appeared, and added much to his fame, which was still further increased by his three best works, *Le jeune Henri*, *Uthal*, and *Joseph*, the finest of the series. He had been appointed one of the four inspectors of the Paris Conservatory, but that office made him feel continually the insufficiency of his early studies, a want which he endeavoured to remedy by incessant application. *Timoléon*, *Ariodant*, and *Bion* followed *Stratonice*, with various success. *Uthal* can scarcely be expected to live, since, by desire of Napoleon Bonaparte, it was written for an orchestra without violins. *Épicure* was composed by Méhul and Cherubini jointly; but the superiority of the latter was evident. Méhul's next opera, *L'Irato*, failed. After writing forty-two operas, besides a number of songs for the festivals of the republic, cantatas, and orchestral pieces of various kinds, his health gave way, from an affection of the chest, which terminated his life on the 18th of October 1817.

MEIBOM, Heinrich (1555–1625), was born at Lemgo on December 4, 1555, and died on September 20, 1625, at Helmstädt, where he had held the chair of history and poetry from 1583. He was a writer of Latin verses (*Parodiarum Horatianarum Libri III. et Sylvarum Libri II.*, 1588), and his talents in this direction were recognized by the emperor Rudolph II., who ennobled him and made him poet laureate in 1590; but his claim to be remembered rests entirely on his services in elucidating the mediæval history of Germany. His *Opuscula Historica ad res Germanicas spectantia* were edited and published in 1660 by his grandson, Heinrich Meibom (1638–1700), who also was professor of history and poetry at Helmstädt, and incorporated the grandfather's work with his own *Rerum Germanicarum Scriptores* (1688).

MEININGEN, the capital of the little duchy of Saxe-Meiningen, in central Germany, and the seat of the provincial courts for Saxe-Meiningen, Saxe-Coburg, and the Prussian districts of Schmalkalden and Schleusingen, is situated on the right bank of the Werra, about 40 miles to the south of Eisenach. It consists of an old town and several handsome suburbs, but much of the former has been rebuilt in a modern style since a destructive fire in 1874. The chief buildings are the Elisabethenburg, or old ducal palace, dating chiefly from 1682, and containing several collections; the new palace; the new town-house; the post-office; the barracks; and the old town church, with its two towers, erected in 1003. The theatre has lately attained a European reputation for its admirably drilled actors and unexcelled scenic effects. The English Garden, a beautiful public park, contains the ducal mortuary chapel and several monuments. The industries, consisting of brewing and the weaving of woollen and cotton cloth, are insignificant. The population in 1880 was 11,227.

Meiningen, which was subject to the bishops of Würzburg for upwards of 500 years (1000–1542), came into the possession of the dukes of Saxony in 1583. At the partition of 1660 it fell to the share of Saxe-Altenburg, and in 1680 it became the capital of Saxe-Meiningen.

MEISSEN, an ancient and important industrial town of Saxony is situated on the left bank of the Elbe, between the streams Meisse and Triebisch, in the district and about 9 miles to the north-west of the town of Dresden. Its irregular hilly site and numerous fine old buildings give it a quaint and picturesque appearance, and most of the streets are narrow and uneven. The cathedral, one of the finest Early Gothic edifices in Germany, is conspicuously situated on the Schlossberg, 160 feet above the town. It is said to have been originally founded by the emperor Otho I., but the present building was begun in the 13th century, and completed soon after 1400. The lofty tower dates from the 15th century. Within the cathedral are the tombs of several Saxon princes of the 15th and 16th centuries, including those of Albert and Ernest, the founders of the present reigning lines. Adjoining the cathedral stands the castle, dating originally from 1473–81, but restored and named Albrechtsburg in 1676. Another thorough restoration was undertaken in 1863, when a series of historical frescos by celebrated modern artists was begun upon its walls. An old stone bridge of the 13th century connects the Schlossberg with the Afraberg, which owes its name to the old convent of St Afra. The convent was suppressed by Duke Maurice in 1543, and converted into the "Fürstenschule," one of the most renowned schools in Germany, counting Lessing and Gellert among its former pupils. The other chief buildings are the town-house, built in 1479, and restored in 1875; the fine old town church, also called the Frauenkirche or Marienkirche; and the churches of St Francis, St Nicholas (coeval with the town), and St Afra. Since 1710, immediately after Böttcher's great discovery, Meissen has been the seat of the manufacture of the so-called Dresden china. Till 1863 the porcelain factory was in the Albrechtsburg, but in that year it was transferred to a large new building in the Triebischthal, close to the town, where about six hundred and seventy hands are now employed. Meissen also contains iron foundries, manufactories of earthenware stoves and pottery, a jute-mill, sugar-refineries, breweries,

tanneries, &c. A considerable trade is carried on in the wine produced in the surrounding vineyards. The population in 1880 was 14,166.

Meissen, one of the oldest and most interesting towns in Saxony, was founded by the emperor Henry I. in 928 as an outpost against the Wends, and became the capital of a margraviate, which was afterwards merged in the duchy of Saxony. Its margraves were among the most powerful mediæval princes in Germany, and were the direct ancestors of the present royal house of Saxony. From 965 till 1581 Meissen was also the seat of an important line of bishops, who ranked as princes of the empire. The town suffered greatly from the Hussites in the 15th century, and it was captured by the imperial troops in the war of the Smalkaldian League, and again in the Thirty Years' War. In 1637 it was severely handled by the Swedes, and in 1745 it fell into the hands of the Prussians.

See *Die Stadt Meissen und ihre Umgegend*, 1855; and H. Herbst's *Praktischer Wegweiser durch die Stadt Meissen*, 1878.

MEKONG, MEKHONG, or MAKONG, less frequently NAM-KONG, the Da-Kio of the Tibetans, the Lantsang-Kiang or Lankiang of the Chinese, and the Son-Kong of the Anamese, sometimes also called the Cambodia or Camboja, is one of the largest and most remarkable rivers of southern Asia. As it rises in Tibet, probably about 34° N. lat. and 94° E. long., and reaches the China Sea about 10° N. lat., after a somewhat devious course through Yunnan, Burmah, Siam, Cambodia, and Cochin-China, its total course may be safely stated at 2000 miles. In spite, however, of this great length, the Mekong must be regarded as little more than a mountain torrent on an unusually large scale. It certainly forms a very extensive delta (see COCHIN-CHINA, vol. vi. pp. 93, 94), and is navigable for steamboats as far up as Cratieh (about 280 miles from the river mouth), but navigation soon becomes difficult, not through want of water, but from the great irregularity of the bed. At Stung-Streng the river measures about 2 leagues from bank to bank, and its current is strong even to violence; it "twists into the sharpest eddies, and drives against the banks with fury." A little higher up are the great cataracts of Kong. Beyond these the channel again becomes navigable as far as Bassac, when it is still about 6500 feet in width; but before long the banks close in and the river, narrowed to about 900 feet, pours along a current of extraordinary depth. Above Khemarat the rapids again begin. At Paklay, Mouhot describes the Mekong as larger than the Menam at Bangkok, forcing its way between the lofty mountains with a noise like the roaring of the sea. About 130 miles farther up, at Luang-Prabang, it has again an unobstructed channel about 3000 feet wide; above Sien-kong the river winds through a magnificent plain; but soon afterwards, in spite of its volume of water, it becomes less navigable than before. The great French expedition of 1866–67 touched its course only at one place higher up, Sien-hong; but other travellers have crossed it at various points in Yunnan. Mr Grosvenor found it, near Yung-feng-chang, at a height of 4700 feet above the sea, a stream of from 60 to 80 yards wide, flowing smoothly and steadily in the floor of a deep gorge (see Coleborne Baker, "Trav. and Res. in Western China," *Roy. Geog. Soc. Suppl. Papers*, 1882). It is there crossed by an iron suspension bridge, of Chinese workmanship, consisting of twelve chains with links about 1 foot long (see Gill, *River of Golden Sand*, vol. ii. p. 330). Higher up, near Tse-ku mission-station, lies the terrific defile to which Cooper (*Trav. of a Pioneer of Commerce*, 1871) gave the name of Hogg's Gorge. The head waters of the Mekong have never been traced to their source; but Huc and Gabet saw the confluence of the two main branches at Tsiamdo (32° N. lat.), and the abbé Desgodins has followed the stream from that point down to Ye-tche in 27° 20′ N. lat. (see *La Mission du Thibet*, Paris, 1872, and the abbé's papers in *Bull. Soc. Géog.*, 1871, 1875, 1876, and 1877). At Yerkalo he observed a curious phenomenon: a number of wells from 12 to 24 feet deep were sunk down among the granite pebbles which form the bed of the river, just above mean-water mark; and they all yielded water with a greater or less degree of saltness and warmth. They are covered when the river is in full flood. The river basin in all the upper section is extremely narrow, being separated by long lines of high mountains from the valley of the Salwin on the west and from that of the Chin-sha-kiang or River of Golden Sands on the east. Not till the comparatively low country of Siam is reached are there any affluents of considerable size. The most important are the Se-mún and the Udong on the right, and the Attopeu or Se-Kong on the left. The Se-mún or Ubon river was explored as far as Korat by the Lagrée expedition, and its tributary the Se-dóm has been followed by Dr Harmand (*Bull. Soc. Géog.*, 1877). Both streams have a rapid and interrupted course. Like the Nile, the Mekong is subject to a great annual inundation, described as early as the 16th century by Camoens, who calls the river Mecom. At some places the difference between flood-mark and ordinary level is from 35 to 40 feet (see COCHIN-CHINA). The first Europeans to make true acquaintance with the river course were the Dutchman Wusthoff and his fellow ambassadors, who in 1641 ascended as far as Winkyan, *i.e.*, Vienchang; their narrative is given by Valentijn, and might have been enough to suggest that the Mekong could not form a trade route to the interior. For the French exploration which finally settled the question, see Garnier's *Expédition*, &c., 1873, and the notice of Garnier in vol. x. p. 82.

MELA, POMPONIUS, a Roman writer on geography. His little work, though a mere compendium, is the only systematic treatise on the subject preserved to us in the Latin language, with the exception of that which forms part of the encyclopædic work of the elder Pliny, and from this circumstance it derives a value to which it would be little entitled from its intrinsic merits. Nothing is known of the author except his name, and that he was born, as he himself informs us, at a small town called Tingentera in the south of Spain. But the date of his work may be fixed with little doubt from an allusion in the preface to a proposed expedition of the reigning emperor to Britain, which can hardly be referred to any other event than the visit to that island of the emperor Claudius in 43 A.D. This conclusion is accepted by all the recent editors; the view of some earlier scholars, who understood this passage as referring to the expedition of Julius Cæsar, is clearly disproved by the mention of several facts which were not anterior to the reign of Augustus. The little treatise is not only a mere abridgment, occupying less than one hundred pages of ordinary print, but is so deficient in method and systematic character that we should have supposed it to be little more than a mere schoolbook, were it not that we find the name of the author figuring in a prominent manner among the authorities cited by Pliny for the geographical books of his vast compilation.

His general views of the geography of the earth do not differ materially from those which were current among Greek writers from the time of Eratosthenes to that of Strabo, and are well known to us from the great work of the latter author, which was, however, in all probability unknown to Mela, as it certainly was to Pliny. But in one of his views he stands alone among ancient writers on geography, that after describing the division of the earth into five zones, of which two only were inhabitable, he states as an undoubted fact the existence of *antichthones*, who inhabited the southern temperate zone, but were inaccessible and consequently unknown to the inhabitants of the corresponding zone in the north, on account of the excessive heat of the intervening torrid zone. His views

of the division and boundaries of the three continents of Europe, Asia, and Africa coincide with those of Eratosthenes; and, in common with all ancient geographers from the time of Alexander to that of Ptolemy, he regarded the Caspian Sea as an inlet from the Northern Ocean, corresponding to the Persian Gulf on the south. His ideas concerning India are extremely confused and imperfect,—altogether inferior to those possessed by Greek writers long before; he follows Eratosthenes in supposing that country to occupy the south-eastern angle of Asia, whence the coast trended northwards to Scythia, and then swept round to the westward to the opening of the Caspian Sea. As usual he places the Rhipæan Mountains and the Hyperboreans near the Scythian Ocean, which he of course connects with that supposed to exist to the north of Europe.

With regard to the west of Europe, on the other hand, his knowledge was somewhat in advance of the Greek geographers, as might be expected from the extension of the Roman dominion and civilization in that quarter, and from a writer who was himself a native of Spain. Accordingly we find him possessing a more accurate idea than either Eratosthenes or Strabo of the western coast-line of Spain and Gaul, and its deep indentation by a gulf (the Bay of Biscay) between the projecting headlands of the two countries. Of Britain, on the contrary, he has little to tell us, beyond what we find in Cæsar or Strabo, though he appears to have had a clearer idea of the position of the British Islands than the Greek geographer. He is also the first ancient writer who mentions the name of the Orcades or Orkneys, which he correctly describes as a large group of islands to the north of Britain. Of the north of Europe his knowledge was still utterly imperfect; but he had a vague notion of the existence to the north of Germany of a large bay, which he calls Codanus Sinus, containing many islands, large and small, among which was one much larger than the rest, which he calls Codanovia,[1]—evidently the same name that reappears in Pliny under the form Scandinavia, which has been attached by modern writers to the great northern peninsula of Europe.

The method followed by Mela in describing the three continents is peculiar and inconvenient. Instead of treating each continent separately, and describing the countries included in it, he begins at the Strait of the Columns (the Straits of Gibraltar), which was close to his own birthplace, and describes the countries adjoining the south coast of the Mediterranean from Mauretania to Egypt, and afterwards those around the east coast of the same sea with its tributary the Euxine, and then back along the north of the Mediterranean from Scythia to Gaul and Spain. He then begins again with the countries bordering the western and northern ocean from Spain and Gaul round to India, and from thence by Persia and Arabia to the Ethiopians, and thence again round Africa to the straits from which he began. In common with most ancient geographers, he considered Africa as surrounded by the sea, but had a very inadequate idea of its extent towards the south.

[1] The first edition of Pomponius Mela was published in 1471, and it was very often reprinted in the 15th and 16th centuries. The edition of Voss in 1658, with a valuable commentary, became the foundation of all the subsequent editions, of which those by Gronovius (in 1685 and 1742) are among the best-known and most useful. The edition by Tzschucke, in 6 vols. 8vo (1806), contains an overwhelming mass of notes and commentaries, but by far the best text is that of the recent edition by G. Parthey (Berlin, 1867), who has in many instances restored the original readings, which had been displaced by the conjectures of Voss and others. (E. H. B.)

MELANCHTHON, Philip (1497–1560), was born at Bretten, a town of the lower Palatinate, on February 16, 1497. His father, George Schwartzerd, was a kinsman of the famous Reuchlin, and by profession an armourer or commissary of artillery under the Palatinate princes. His mother, Barbara Reuter, was a thrifty housewife and affectionate parent, whose pious character is evidenced by a well-known German rhyme, of which she is the reputed author, beginning *Almosen geben armet nicht*. His mother's father, John Reuter, who was for many years mayor of Bretten, charged himself with the education of Philip. Taught first by John Hungarus, then by George Simler at the academy of Pfortzheim, where he lived in the house of Reuchlin's sister, young Schwartzerd exhibited remarkable precocity, and speedily won the regard of Reuchlin, who dubbed him Melanchthon (the Greek form of Schwartzerd), according to the fashion of that age. He lived two years at Heidelberg, and the next three at Reuchlin's university of Tübingen, where he studied law, medicine, and theology, taking his doctor's degree in 1514. He began soon after to give public lectures on rhetoric, and to comment on Virgil and Terence, and ere long it became known among European scholars that a new brilliant star of learning had risen on the horizon, Erasmus prophesying that he would himself be speedily eclipsed. In 1518, on Reuchlin's recommendation, Melanchthon was appointed by the elector of Saxony professor of Greek in the university of Wittenberg. This appointment marked an epoch in German university education; Wittenberg became the school of the nation; the scholastic methods of instruction were summarily set aside, and in a *Discourse on Reforming the Studies of Youth* Melanchthon gave proof, not only that he had thoroughly caught the Renaissance spirit, but that he was fitted to become one of its foremost leaders. He began to lecture on Homer and the Epistle to Titus, and in connexion with the former he announced that, like Solomon, he sought Tyrian brass and gems for the adornment of God's temple. Luther himself received a fresh impulse towards the study of Greek, and his translation of the Scriptures, begun as early as 1517, now made rapid progress, Melanchthon helping to collate the Greek versions and revising Luther's translation. Melanchthon on his part felt the spell of Luther's large personality and spiritual depth, and he seems to have been prepared on his first arrival at Wittenberg to accept the new theology, which indeed as yet existed mainly in subjective form, and as a living spiritual force, in the person of Luther. To reduce it to an objective system, to exhibit it dialectically, the calmer mind of Melanchthon, with its architectural faculty and delicate moral tact, was requisite. Theologically it is impossible to separate Melanchthon from Luther; "the miner's son drew forth the metal, the armourer's son fashioned it." Luther, in whom courage and energy were too much akin to violence and zealous decision to narrow intolerance, and Melanchthon, whose calm deliberation was apt to degenerate into vacillation and whose conciliatory temperament was too much allied to timidity, were each the fit complement of the other.

Melanchthon was first drawn into the arena of the Reformation controversy through the Leipsic discussion, of which he was an eager spectator. He had been sharply reproved by Dr Eck for giving aid to Carlstadt ("Tace tu, Philippe, ac tua studia cura nec me perturba"), and he was shortly afterwards himself attacked by the blustering Ingolstadt doctor. Melanchthon replied in a brief treatise—a model of Christian moderation—setting forth Luther's first principle of the supreme authority of Scripture in opposition to the patristic writings on which Eck so boastfully relied. His marriage in 1520 to Catherine Krapp of Wittenberg increased his own happiness, and gave a domestic centre to the Reformation. In 1521, during Luther's confinement in the Wartburg, Melanchthon occupied the important position of leader of the Reformation cause at the university. He defended the action of the Augustinian monks when they substituted for the celebration of the mass the sacrament of the supper partaken of by

the people under both kinds; but, on the advent of the Anabaptist enthusiasts of Zwickau, he had a still more difficult part to play. Melanchthon was irresolute. In their attacks upon infant baptism they seemed to him to have hit upon a "weak point"; and in regard to their claim to personal inspiration his position was summed up in his own words, "Luther alone can decide; on the one hand let us beware of quenching the Spirit of God, and on the other of being led astray by the spirit of Satan." In the same year he published his *Loci Communes Rerum Theologicarum*.

After the first diet of Spires (1526), where a precarious peace was patched up for the Reformed faith, Melanchthon was deputed as one of twenty-eight commissioners to visit the Reformed states and regulate the constitution of churches, he having just published a famous treatise called the *Libellus Visitatorius*, a directory for the use of the commissioners. At the Marburg conference (1529) between the German and Swiss Reformers, Luther was pitted against Œcolampadius and Melanchthon against Zwingli in the discussion regarding the real presence in the sacrament. How far the candid conciliatory spirit of Melanchthon was biassed by Luther's intolerance is evident from the exaggerated and inaccurate accounts of the conference written by the former to the elector of Saxony. At the diet of Augsburg (1530) Melanchthon was the leading representative of the Reformation. With anxiety and tears he drew up for that diet the seventeen articles of the evangelical faith, which are known as the "Augsburg Confession." He held conferences with Romish divines appointed to adjust differences, and afterwards wrote an *Apology for the Augsburg Confession*. After the Augsburg conference further attempts were made to settle the Reformation controversy by a compromise, and Melanchthon, from his conciliatory spirit and facility of access, appeared to the Romanists the fittest of the Reformers to deal with. His historical instinct led him ever to revert to the original unity of the church, and to regard subsequent Romish errors as excrescences rather than proofs of an essentially anti-Christian system. He was weary of the *rabies theologorum*, and fondly dreamed that the evangelical leaven, if simply tolerated, would at length purify the church's life and doctrine. In 1537, when the Protestant divines signed the Lutheran Articles of Smalkald, Melanchthon appended to his signature the reservation that he would admit of a pope provided he allowed the gospel and did not claim to rule by divine right.

The year after Luther's death, when the battle of Mühlberg (1547) had given a seemingly crushing blow to the Protestant cause, an attempt was made to weld together the iron and clay of the evangelical and the papal doctrines, which resulted in the compilation by Pflug, Sidonius, and Agricola of the Augsburg "Interim." This was proposed to the two parties in Germany as a provisional ground of agreement till the decision of the council of Trent. Melanchthon, on being referred to, declared equivocally that, though the Interim was inadmissible, yet so far as matters of indifference (*adiaphora*) were concerned it might be received. Hence arose that "adiaphoristic" controversy in connexion with which he has been misrepresented as holding among matters of indifference such cardinal doctrines as justification by faith, the number of the sacraments, as well as the dominion of the pope, feast-days, and so on. The fact is that, in these tentative negotiations, Melanchthon sought, not really to minimize differences, but to veil them under an intentional obscurity of expression. Thus he allowed the necessity of good works to salvation, but not in the Romish sense, proposed to allow the seven sacraments, but only as rites which had no inherent efficacy to salvation, and so on. He afterwards retracted his compliance with the adiaphora, and never really swerved from the views set forth in the *Loci Communes*; but he regarded the surrender of more perfect for less perfect forms of truth or of expression as a painful sacrifice rendered to the weakness of erring brethren. Luther, though he had uttered certain expressions of dissatisfaction with Melanchthon, and had more keenly defended in his last years what was distinctively his own, yet maintained hearty and unbroken friendship with him; but after Luther's death certain smaller men arose in name of Luther who formed a party emphasizing the extremest points of the doctrine of the latter. Hence the later years of Melanchthon were much occupied with acrid controversies within the evangelical church; an account of these, however, would be out of place here. His last years were spent in fruitless conferences with his Romanist adversaries, and amid various controversies among the Reformed, but the flame of his piety burnt brightly till the close. He died in his sixty-third year, on the 19th April 1560, and his body was laid beside that of Martin Luther.

Melanchthon's ever ready pen, clear thought, and elegant style made him the scribe of the Reformation, most public documents on that side being drawn up by him. He never attained entire independence of Luther, though he gradually modified some of his positions from those of the pure Lutherism with which he set out. His development is chiefly noteworthy in regard to these two leading points—the relation of the *evangelium* or doctrine of free grace (1) to free will and moral ability, and (2) to the law and *pœnitentia* or the good works connected with repentance. At first Luther's cardinal doctrine of grace appeared to Melanchthon inconsistent with any view of free will; and, following Luther, he renounced Aristotle and philosophy in general, since "philosophers attribute everything to human power, while the sacred writings represent all moral power as lost by the fall." In the first edition of the *Loci* (1521) he held, to the length of fatalism, the Augustinian doctrine of irresistible grace, working according to God's immutable decrees, and denied freedom of will in matters civil and religious alike. In the Augsburg Confession (1530), which was largely due to him, freedom is claimed for the will in non-religious matters, and in the *Loci* of 1533 he calls the denial of freedom Stoicism, and holds that in justification there is a certain causality, though not worthiness, in the recipient subordinate to the Divine causality. In 1535, combating Laurentius Valla, he did not deny the spiritual incapacity of the will *per se*, but held that this is strengthened by the word of God, to which it can cleave. The will co-operates with the word and the Holy Spirit. Finally, in 1543, he says that the cause of the difference of final destiny among men lies in the different method of treating grace which is possible to believers as to others. Man may pray for help and reject grace. This he calls free will, as the power of laying hold of grace. Melanchthon's doctrine of the three concurrent causes in conversion, viz., the Holy Spirit, the word, and the human will, suggested the semi-Pelagian position called Synergism, which was held by some of his immediate followers.

In regard to the relation of grace to repentance and good works, Luther was disposed to make faith itself the principle of sanctification. Melanchthon, however, for whom ethics possessed a special interest, laid more stress on the law. He began to do this in 1527 in the *Libellus Visitatorius*, which urged pastors to instruct their people in the necessity of repentance, and to bring the threatenings of the law to bear upon men in order to faith. This brought down upon him the opposition of the Antinomian John Agricola. In the *Loci* of 1535 Melanchthon sought to put the fact of the co-existence of justification and good works in the believer on a secure basis by declaring the latter necessary to eternal life, though the believer's destiny thereto is already fully guaranteed in his justification. In the *Loci* of 1543 he did not retain the doctrine of the necessity of good works in order to salvation, and to this he added, in the Leipsic Interim, "that this in no way countenances the error that eternal life is merited by the worthiness of our own works." Melanchthon was led gradually to lay more and more stress upon the law and moral ideas; but the basis of the relation of faith and good works was never clearly brought out by him, and he at length fell back on his original position that we have justification and inheritance of bliss in and by Christ alone, and that good works are necessary by reason of immutable Divine command.

Melanchthon's life has been written by Camerarius. See also Matthes, *Ph. Melanchthon, sein Leben und Wirken*, 1841; Galle, *Charakteristik Melanchthons als Theologen*, Halle, 1845; Rothe's *Gedächtnissrede auf Melanchthon*, 1860; Nitzsch, *Melanchthon*, 1860; Schmidt, *Melanchthons Leben*, 1864. There is a biography in English by F. A. Cox, 2d ed., London, 1817. The works of Melanchthon, including his correspondence, are contained in the voluminous *Corpus Reformatorum*, edited by Bretschneider and Bindseil. (J. W.)

**MELANESIA.** This term comprises that long belt of island groups which, beginning in the Indian archipelago at the east limits of the region there occupied by the Malay race, and, as it were, a prolongation of that great island region, runs south-east for a distance of some 3500 English miles, *i.e.*, from New Guinea at the equator, in 130° E. long., to New Caledonia just within the Tropic, 167° E. long., and eastwards to Fiji, in 180°. This chain of groups has a certain geographical as well as ethnical unity. Its curve follows roughly the outline of the Australian coast, and large islands occur, with a number of small ones, along the whole length, with mountains of considerable height, coinciding pretty closely with a line of volcanic action. Melanesia is usually held to begin with New Guinea, this great island being then viewed as the headquarters of that dark Papuan race which, widely and variously modified in all the other groups, occupies the whole region, as the name Melanesia implies; but the race really extends farther west, for the large islands Flores and Timor, with several smaller ones, are also essentially Papuan.

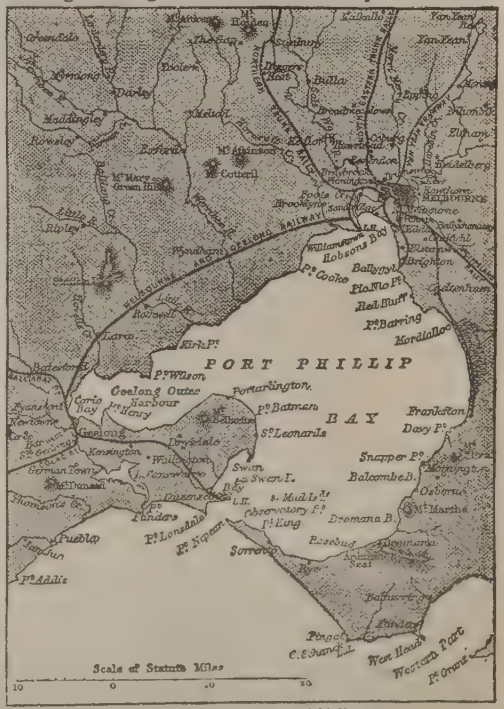
New Guinea, 1490 miles long, and containing about 303,000 square miles, the largest island in the world after Australia, is clothed with almost impenetrable forests, through which mountain ranges rise to a height of 13,000 feet. Parallel to its longer axis, 150 miles to the north, are the Admiralty Islands, all small, with one exception, in which the hills rise to 1600 feet, and which is probably of volcanic origin, as the natives use spearheads and implements of obsidian. A Polynesian element seems to be present, and customs peculiar to both races have been observed. Mr H. N. Moseley, of the "Challenger," found them shrewd but honest traders, with much artistic skill in their carvings and designs. They have numerals up to 10, with an idiom for 8 and 9, viz., 10–2 and 10–1, which is found also at Yap in the Carolines, and in the Marshall Islands.

Next follow, east, the two large islands of New Britain, about 340 by 23 English miles, with active volcanoes up to 4000 feet, and New Ireland, about 240 by 22 miles. Next comes the Solomon group, 600 English miles in length, with seven large islands from 135 to 90 miles long, all running north-west and south-east, with volcanic peaks up to 8000 feet. The forms more characteristic of the New Guinea fauna do not extend beyond this group. Its forest vegetation is especially luxuriant. Then comes Santa Cruz, a small group partly volcanic, but with numerous coral reef islands. Then the Banks and New Hebrides group, over 500 English miles in length, all volcanic except the Torres reef islands in the north. Several spots in this group are occupied by people of purely Polynesian race, immigrants apparently from the eastward. Two hundred miles south-west from the New Hebrides lies the island of New Caledonia, about 240 by 25 English miles. It is in parts very mountainous, rising to 5380 feet, the rocks being sedimentary and plutonic, but there are no volcanoes. It lies half way between Australia and Fiji, 700 miles from each. Being outside the equatorial belt, it is much drier and more barren than the other groups, and its fauna and flora have many Australian and Polynesian affinities. The small Loyalty chain lies 70 miles east of New Caledonia, and parallel to it. Fiji is detached from the other Melanesian groups, and differs from them in various particulars. It consists of two large and about 300 small islands, the total area being about 7400 square miles.

Of the two great Pacific races—the brown Polynesian, and the dark Melanesian—the former, considering the vast region it occupies, is singularly homogeneous both in appearance and language, whereas in Melanesia even neighbouring tribes differ widely from each other in both respects. Still, all the Melanesians have certain common characteristics which distinguish them sharply from the other race. They stand at a lower level of civilization, as is well seen at certain spots in Melanesia where isolated Polynesian settlements exist, due probably to voluntary migration, and where the two races, though they have some peculiar customs in common, live in bitter mutual hostility. The Melanesians are mostly "negroid" in appearance, nearly black, with crisp curly hair elaborately dressed; the women hold a much lower position than among the Polynesians; their institutions, social, political, and religious, are simpler, their manners ruder and often indecent; they have few or no traditions; cannibalism, in different degrees, is almost universal; but their artistic skill and taste, as with some of the lower African negroes, are remarkable, and they are amenable to discipline and fair treatment. Their languages, amid considerable differences, which, as between the Melanesian proper and the Papuan, are very wide, have features which mark them off clearly from the Polynesian, notwithstanding certain fundamental relations with the latter.

The various Melanesian groups will be found described in detail under separate headings.

**MELBOURNE**, the capital of the colony of Victoria, and the most populous city in Australia, is situated at the head of the large bay of Port Phillip, on its northern bend known as Hobson's Bay, about 500 miles S.W. of Sydney by land and 770 by sea, the position of the observatory being 37° 49′ 53″ S. lat. and 144° 58′ 42″ E. long. Along the shores of the bay the suburbs



Port Phillip and Environs of Melbourne.

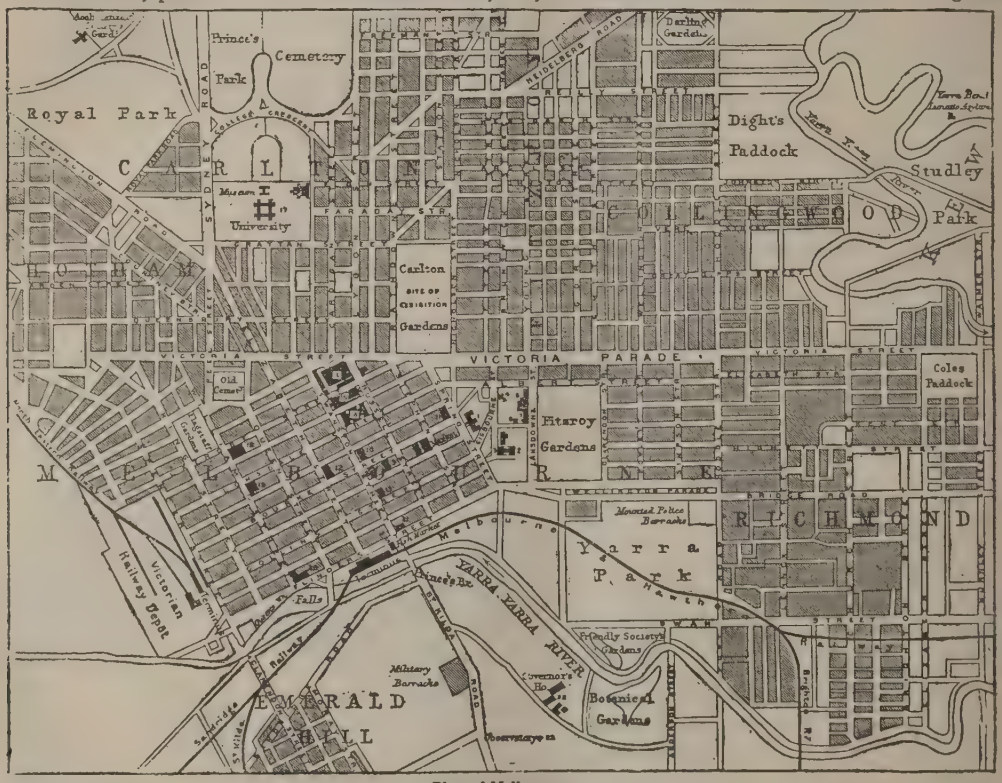
extend for a distance of over 10 miles, but the part distinctively known as the "city" occupies a site about 3 miles inland on the north bank of the Yarra river.

The appearance of Melbourne from the sea is by no means picturesque. The shipping suburbs of Sandridge and Williamstown occupy the alluvial land at the mouth

of the Yarra, and, as the district is low and flat, and covered with factories, the prospect is not inviting. But the city itself has a very different aspect: its situation is relieved by numerous gentle hills, which show off to great advantage its fine public buildings; its streets are wide and well kept; and the universal appearance of prosperity, activity, and comfort under its usually clear blue sky impresses the visitor favourably.

That part specially known as the "city" had a population in 1881 of 65,800. It occupies the two hills of East Melbourne and West Melbourne; the valley that separates them, once occupied by a densely wooded little stream, is now partly filled in, and forms the busy thoroughfare of Elizabeth Street; parallel to this runs Swanston Street, and at right angles to these, and parallel to the river, are Bourke Street, Collins Street, and Flinders Street,—the first being the busiest in Melbourne, the second containing the most fashionable shops, and the third, which faces the river, being given over to maritime pursuits. These streets are the eighth of a mile apart; between them are narrower streets occupied by warehouses and business premises.

Round the "city" lies a circle of populous suburbs. North-east is Fitzroy with 23,000 inhabitants; farther east, Collingwood, 24,000; east of Melbourne, Richmond, 23,400; south-east, Prahran, 21,000; south, Emerald Hill, 25,300; south-west, Sandridge, 8700; north-west, Hotham, 17,800. These all lie within three miles of the general



Plan of Melbourne.

1. Houses of Parliament.
2. Treasury.

post-office in Elizabeth Street; but outside of them, and within a radius of 5 miles, there is a circle of less populous suburbs: to the north, Brunswick, 6200; east, Kew, 4200, and Hawthorn, 6000; south-east, St Kilda, 11,600, and Brighton, 4700; south-west, Williamstown, 9000, and Footscray, 6000; north-west, Essenden and Flemington, 5000. Numerous smaller suburbs fill up the spaces between these,—the principal being Northcote, Preston, Camberwell, Toorak, Caulfield, Elsternwick, and Coburg, with a united population of 19,000.

Fifteen of these suburbs rank as independent municipalities, and many of them have streets which for importance rival the main streets of the city.

The following table shows the growth of the population since 1851:—

| | 1881. | | | Total. | | |
|---|---|---|---|---|---|---|
| | Male. | Female. | Total. | 1871. | 1861. | 1851. |
| Melbourne | 34,526 | 31,333 | 65,859 | 54,993 | | |
| Suburbs | 113,785 | 103,263 | 217,048 | 151,787 | | |
| Total | 148,311 | 134,596 | 282,907 | 206,780 | 191,254 | 25,000 |

The land on which the city now stands was sold in allotments of half an acre, the prices realized being in June 1837 about £34 each, in November 1837 about £42, and in September 1838 about £120 each. These allotments are now (1882) sold at prices ranging from £20,000 to £40,000. But, though land has thus increased in value, Melbourne is by no means a crowded city; the streets are all 99 feet wide, and the parks, squares,

and gardens are so numerous that with only one-thirteenth of the population of London it occupies very nearly half as great an area.

The public buildings are generally situated on positions from which they are seen to advantage. The Parliament Houses form a great pile of brickwork with four fronts in freestone, of which the main front is not yet completed; the interior decorations are highly elaborate. The Treasury is a well-proportioned building in freestone; behind it stands a vast building known as the Government offices. On the hill of West Melbourne there is a large structure, newly erected, for the law courts; it has four very handsome fronts, each about 300 feet in length, and the whole is surmounted by a lofty cupola, in the manner of the Capitol at Washington. The public library in Swanston Street forms one of four fronts of a building which was projected on a grand scale, but has never been completed. Much of the interior has been erected, but of the fronts only the main one is yet in existence, its cost having been £111,000. The lower story is devoted to sculpture; on one side there are casts of all the most famous statues; on the other there is a small collection of original works by modern sculptors, together with a gallery containing 8000 engravings and photographs; to the rear is the picture gallery, a very handsome hall, with oil paintings, chosen from the works of living artists. Another of the interior portions of the building is occupied by the technological museum, in which are arranged about 30,000 specimens illustrative of the industrial arts. The upper story of the front is devoted to the library, which occupies a chamber 240 feet long; 22 recesses contain each its own special branch of literature, the total number of volumes being 112,000. The book shelves rise to a height of 20 feet, but they are divided by a narrow gallery which runs all round the room, and gives access to the upper tiers. The library is open to the public; and every visitor ranges at will, being bound by the two conditions only that he is to replace each book where he found it, and that he is to preserve strict silence. During 1881 there were 261,886 visits made to the room.

The Melbourne University is a picturesque, but by no means imposing mass of buildings, buried among the trees of extensive and well-kept grounds about a mile from the heart of the city. In front of it stands the "Wilson Hall," erected at a cost of £40,000. Behind is the National Museum, containing collections of specimens of natural history. The museum, like all public places in Melbourne, is freely open to the people. About 98,000 visitors entered it in 1881. The university has a staff of 10 professors and 12 lecturers, with about 400 students. There are four courses open to students: arts, law, medicine, and civil engineering. Affiliated to the Melbourne University are the two denominational colleges, Trinity and Ormond, in which about 80 students reside, and where provision is made for instruction in theology.

The Exhibition building consists of a nave 500 feet long and 160 feet broad, surmounted by a dome, with two annexes each 460 feet long. These are built in brick with cement facings. The mint is a very handsome quadrangle, erected in 1872. In the year 1881 there were three millions of sovereigns coined in it, making a total of sixteen millions since its erection. The governor's residence is a large building on a hill overlooking the Yarra. The general post-office forms only half of a magnificent pile of buildings which will, when completed, include the central telegraph office.

The town-hall, at the corner of Swanston Street and Collins Street, contains, besides the usual apartments for municipal offices, a hall seated for nearly 3000 persons, and fitted with a colossal organ, on which the city organist performs two afternoons a week, the public being admitted at a nominal charge. Hotham, Richmond, Emerald Hill, Prahran, and Fitzroy have their own town-halls, all costly and somewhat pretentious buildings.

The markets, erected at a cost of £80,000, stand in Bourke Street. They are handsome in external appearance, and ingeniously contrived for convenience within. The observatory is a humble-looking building on the St Kilda Road; it contains an equatorial telescope, which had for some years the distinction of being the largest in the world.

There are two railway stations, one being the terminus of all the country lines, and the other devoted to suburban traffic. The suburbs of Williamstown, Sandridge, Footscray, St Kilda, Emerald Hill, Brighton, Elsternwick, Hawthorn, Richmond, and Essendon are connected by rail with the city.

The Melbourne Hospital is in the form of an extensive series of brick buildings, situated close to the public library. There are beds for about 300 patients. The Alfred Hospital, on the St Kilda Road, was built in commemoration of the visit of Prince Alfred; it has beds for nearly 100 patients. The lying-in hospital can accommodate 62 persons. The blind asylum has over 100 inmates; and there are a deaf and dumb asylum, an immigrants' home, and other charitable institutions.

Melbourne contains many churches, but few of them will compare with the public buildings in appearance. The Roman Catholic cathedral of St Patrick, when completed, will, however, be a conspicuous ornament to the city. The Anglican cathedral, now (1882) in the course of erection, is to cost about £100,000. The most striking ecclesiastical building is the Scotch church in Collins Street, which divides with Ormond College and the Wilson Hall the honour of being the finest specimen of architecture in the city.

There are in Melbourne, among its numerous state schools, about thirty whose size and proportions entitle them to rank with the architectural ornaments of the city. They have each accommodation for from 600 to 2000 scholars. Abundant provision has been made for secondary instruction by the denominations and by private enterprise. The Scotch College and the Presbyterian Ladies' College, the Wesley College and the Wesleyan Ladies' College, the Church of England Grammar School, St Patrick's College and St Francis Xavier's College, are all connected with the churches; and there are besides between twenty and thirty good private grammar schools.

Melbourne contains the offices of numerous banks, savings banks, and building societies.

The parks and public gardens of Melbourne are extensive and handsome. Within the city proper there are four gardens, which have been decorated with a lavish expenditure. The Fitzroy Gardens are one dense network of avenues of oak, elm, and plane, with a "fern-tree gully" in the middle. Casts of famous statues abound; and ponds, fountains, rustic houses, and small buildings after the design of Greek temples give a variety to the scene. The Treasury, Flagstaff, and Carlton Gardens are of the same class, but less costly in their decorations. Around the central city there lie five great parks. The Royal Park, of about 600 acres, is lightly timbered with the original gum trees; some portions of open land are used for recreation. About 30 acres in the centre are beautifully laid out to accommodate a very superior zoological collection. The Yarra Park, of about 300 acres, contains the leading cricket grounds; of these the "Melbourne" is the chief, distinguished by its very large stand and the excellence of its pitch. The Botanic Gardens occupy

about 200 acres of land, sloping down to the banks of the river, and laid out with great taste and skill. Albert Park, about 500 acres in extent, is not so elaborately laid out, but contains a small lake, which is much used for boating purposes, as the bay is stormy and exposed. Studley Park, a favourite place for picnics, is a romantic corner on a bend of the upper Yarra, of about 200 acres extent, left entirely in a state of nature.

Besides these parks each suburb has its own "gardens" of moderate extent. At Flemington a large reserve is devoted to racing purposes, where in November the race for the Melbourne Cup is held, the great racing carnival of Australia, attended by about 100,000 persons.

The shipping of Melbourne is very considerable. In 1880 about 1500 vessels entered and cleared again, their tonnage being 960,000. Nearly all the intercolonial and a small proportion of the foreign vessels ascend the Yarra and unload in the heart of the city. The river was originally navigable for vessels of only 9 feet draught; but of late years the channel has been deepened so much that vessels drawing 16 feet can ascend with safety. Great works are now in operation by which the course is to be straightened and further deepened; and the quays which line the river banks will be made accessible to the large vessels which now have to lie in the bay off the Sandridge and Williamstown piers.

Shipbuilding is a comparatively unimportant industry, but a great deal of repairing is done; the graving dock at Williamstown is able to hold the largest vessels which enter the port.

The total values of the imports of Melbourne for 1879 and 1880 were respectively £15,035,000 and £14,557,000, and of the exports £12,454,000 and £15,954,000.

In 1881 Melbourne contained 2469 factories, employing 38,141 hands, and converting £8,012,745 worth of raw material into £13,384,836 worth of finished articles. The leading products are leather, flour, clothing, furniture, boots, carriages, preserved meats, ales, soap, candles, cigars, ironwork, jewellery, jams, confectionery, biscuits, and woollens.

The city is abundantly supplied with newspapers, including three morning and three evening dailies. Two reviews are published.

The climate of Melbourne is exceptionally fine, the only drawback being the occasional hot winds which blow from the north for two or three days at a time, and raise the temperature to an uncomfortable extent. But the proportion of days when the sky is clear and the air dry and mild is large. The mean annual temperature is 57°, which would make the climate of Melbourne analogous to that of Madrid, Marseilles, or Verona, but without the extremes experienced in those places. Snow falls every year in Italy, while it is unknown in Melbourne; and the highest temperature reached there in summer is below that of the cities mentioned.

As a field for emigration from European countries, Melbourne offers many advantages to the industrious mechanic or labourer.

The cost of living is about the same as in London. Rents are higher, and furniture and utensils dearer; but butcher meat, bread, and clothes are cheaper.

There is no city where more has been done for the working-classes or where they have made so good a use of their advantages. Many of their efforts at government (for they have all the power in their hands) have been ill-advised, but individually they have exhibited a prudence of which the community reaps the fruits. It is one of the peculiar features of Melbourne that about three out of every four mechanics who have reached middle life own the neat cottages they occupy.

*History.*—The city of Melbourne is without exception the most striking instance of the aptitude of the Anglo-Saxon race for colonization. It was not till the opening years of the present century that the first European sailed through the narrow entrance to Port Phillip, and it was only in 1835 that the white man made his habitation there. In that year John Fawkner sailed up the Yarra in his little vessel the "Enterprise," laden with materials for a settlement; he was stopped by a slight waterfall in a valley where dense groves of wattle trees all in bloom loaded the air with perfume, and where flocks of white cockatoos whirled aloft when the first stroke of the axe resounded in the forest. This spot is now the centre of a great city 10 miles in length, 6 in breadth, covering an area of 45,000 acres, and peopled by 283,000 persons. So rapid and solid a growth, at a distance from the mother country of the whole extent of the earth, is an example of colonizing enterprise altogether without parallel.

The settlement was at first called by the native name "Dootigala," but a desire for distinguished patronage caused the portion on the sea-shore, which was then esteemed the more important, to be called "Williamstown," after King William IV., while the little collection of huts some 3 or 4 miles inland was named "Melbourne," in honour of the prime minister Lord Melbourne.

For two years a constant stream of squatters with their sheep flowed in from Tasmania; then numerous "overlanders" drove their flocks from the Sydney side across the Murray and settled near Port Phillip. Captain Lonsdale was sent by the Sydney Government to act as police magistrate, but in 1838 Mr Latrobe was placed in charge with the title of superintendent. As the squatters prospered Melbourne increased in size, so that in 1841 it contained 11,000 inhabitants. A period of depression occurred in 1843, followed by several years of the greatest prosperity, till, in 1851, gold was discovered in New South Wales. The district of Port Phillip became infected by the excitement; many parties scoured that part of the country in search of the precious metal, and six weeks after the first discovery of it there the great riches of Ballarat were made known. Within a year from that time a hundred thousand men had landed in the colony in order to proceed to the diggings; for several years after the same number landed every twelve months; and Melbourne increased in population from 30,000 to 100,000 in the course of two or three years.

During the year of the gold discoveries, the Port Phillip district was separated from New South Wales, and formed into a separate colony with the name Victoria. In 1855 the British Government granted to it a complete autonomy; Melbourne became the capital of the new colony. (A. SU.)

MELBOURNE, WILLIAM LAMB, SECOND VISCOUNT (1779–1848), second son of the first Viscount Melbourne, was born 15th March 1779. After completing his course at Trinity College, Cambridge, he studied law at the university of Glasgow, entered Lincoln's Inn in 1797, and was called to the bar in 1804. In 1805 he married Lady Caroline Ponsonby, daughter of the earl of Bessborough, who after her separation from him acquired some fame as a novelist, and was also a friend of Lord Byron. On entering parliament the same year Lamb joined the opposition under Fox, of whom he was an ardent admirer; but his Liberal tendencies were never of a very decided character, and he not unfrequently gave his support to Lord Liverpool during that statesman's long tenure of office. During the short ministry of Canning in 1827 he was chief secretary for Ireland, but he afterwards for a time adhered to the small remnant of the party who supported the duke of Wellington. The influence of Melbourne as a politician dates from his elevation to the peerage in 1828. Disagreeing with the duke of Wellington on the question of parliamentary reform, he in 1830 entered the ministry of Grey as home secretary. For the discharge of the difficult and multifarious duties of this office at such a critical time he was decidedly deficient both in insight and in energy, but his political success was totally independent of his official capacity; and, when the ministry of Grey was wrecked on the Irish question, Melbourne was chosen to succeed him. Almost immediately he had to give place to a Conservative ministry under Peel, but, the verdict of the country being in his favour, he resumed office in 1835. The period of his ministry was wholly uneventful, and for a considerable time before he resigned in 1841 he had lost the confidence of the

country. From the time of his retirement from office he took little interest in politics. He died at Melbourne House, Derbyshire, 24th November 1848.

Lord Melbourne was without even the elementary qualification of diligent attention to details, which in the absence of higher endowments sometimes confers on a statesman the greater part of his success. Nor can it be said that in public he ever displayed any of those specious and brilliant talents which are often found an acceptable substitute for more solid acquirements. Though he possessed a fine and flexible voice, his manner as a speaker was ineffective, and his speeches were generally ill-arranged and destitute of oratorical point, notwithstanding his occasional indulgence in inelegant flights of rhetoric. Indeed his political advancement was wholly due to his personal popularity. He had a thorough knowledge of the private and indirect motives which influence politicians, and his genial attractive manner, easy temper, and vivacious, if occasionally coarse, wit helped to confer on him a social distinction which for a time led many to take for granted his eminence as a statesman. The most notable and estimable feature of his political conduct is his relation to Queen Victoria, whom he initiated into the duties of sovereign with the most delicate tact and the most friendly and conscientious care.

MELCHIADES, or MILTIADES (other forms of the name being Meltiades, Melciades, Milciades, and Miltides), was pope from July 2, 310, to January 10 or 11, 314. He appears to have been an African by birth, but of his personal history nothing is known. The toleration edicts of Galerius and of Constantine and Licinius were published during his pontificate, which was also marked by the holding of the Lateran synod in Rome (313), at which Cæcilianus was acquitted of the charges brought against him, and Donatus condemned. Melchiades was preceded and followed by Eusebius and Sylvester I. respectively.

MELCHITES. The name of Melchites (Syriac, *Malkâyê*; Arabic, *Malakîya*, or in the vulgar pronunciation *Milkîya*) means etymologically the royal party, and so is currently applied in the East to Syrian and Egyptian Christians of the Orthodox Greek Church, adherents of the creed supported by the authority of the king, that is, of the Byzantine emperor. The Melchites therefore are those who accept the decrees of Ephesus and Chalcedon as distinguished from the Nestorians and Jacobites, and the name reflects in an interesting manner the way in which the doctrinal controversies that agitated the Eastern empire associated themselves with national feelings of antagonism to the imperial rule.

MELCHIZEDEK (מַלְכִּי־צֶדֶק, "king of righteousness"), king of Salem and priest of "supreme El" (*El 'elyôn*), brought forth bread and wine to Abram, on his return from the expedition against Chedorlaomer, and blessed him in the name of the supreme God, possessor (or maker) of heaven and earth. And Abram gave him tithes of all his booty (Gen. xiv. 18–20). The Bible history tells us nothing more about Melchizedek (comp. Hebrews vii. 3); but the majestic figure of the king-priest, prior to the priesthood of the law, to whom even the father of all Israel paid tithes, suggested a figurative or typical application, first in Psalm cx. to the vicegerent of Jehovah, seated on the throne of Zion, the king of Israel who is also priest after the order of Melchizedek, and then, after the gospel had confirmed the Messianic interpretation of the Psalm (Matt. xxii. 42 *sq.*), to the kingly priesthood of Jesus, as that idea is worked out at length in the Epistle to the Hebrews.

The theological interest which attaches to the idea of the pre-Aaronic king-priest in these typical applications is practically independent of the historical questions suggested by the narrative of Gen. xiv. It is generally recognized that this chapter holds quite an isolated place in the Pentateuchal history; it is the only passage which presents Abraham in the character of a warrior, and connects him with historical names and political movements, and there are no clear marks by which it can be assigned to any one of the documents of which Genesis is made up. Thus, while one school of interpreters finds in the chapter the earliest fragment of the political history of western Asia, some even holding with Ewald that the narrative is probably based on old Canaanite records, other critics, as Nöldeke, regard the whole as unhistorical and comparatively late in origin. On the latter view, which finds its main support in the intrinsic difficulties of the narrative, it is scarcely possible to avoid the conclusion that the chapter is one of the latest additions to the Pentateuch (Wellhausen). The historical arguments *pro* and *con* may be seen at length in recent commentaries, but especially in Tuch's essay (*Z. D. M. G.*, i. 161 *sq.*, reprinted in the second edition of his *Genesis*), which was long viewed as decisive in favour of the narrative, and in Nöldeke's *Untersuchungen*, 1869, p. 156 *sq.*, with which compare Wellhausen in *Jahrb. f. D. Th.*, 1876, p. 414 *sq.* The Assyrian monuments offer no decisive evidence, but are held to confirm the historical possibility of the proper names (Schrader, *KI. und AT.*, p. 46 *sq.*; Delitzsch, *Paradies*, p. 224). Here we can only speak of the episode of Melchizedek, which, though connected with the main narrative by the epithets given to Jehovah in verse 22, seems to break the natural connexion of verses 17 and 21, and may perhaps have come originally from a separate source. As the narrative now stands Salem must be sought in the vicinity of "the king's dale," which from 1 Sam. xviii. 18 probably but not necessarily lay near Jerusalem. That Salem is Jerusalem, as in Psalm lxxvi. 2, is the ancient and common view, and is necessarily followed by those who view Melchizedek as a late creation. Those who hold the opposite view now lean to the identification with the Σαλείμ of John iii. 23, 8 miles south of Bethshean, which Jerome (*Ep.* lxxiii. *ad Evangelium*) confirms by a worthless tradition. In a genuine record of extreme antiquity the union of king and priest in one person, the worship of El as the supreme deity by a Canaanite,[1] and the widespread practice of the consecration of a tithe of booty can present no difficulty; but, if the historical character of the narrative is denied, the origin of the conception must be placed as late as the rise of the temporal authority of the high priests after the exile. An ancient legend identifies Melchizedek with Shem (Palestinian Targum, Jerome on Isa. xli., Ephraem Syrus *in loco*).

MELCOMBE REGIS. See WEYMOUTH.

MELENDEZ VALDES, JUAN (1754–1817), minor poet of Spain, was born at Ribera del Fresno, Badajoz, on March 11, 1754. He was destined by his parents, who were in good circumstances, for an official career; and accordingly, after having completed his preliminary education at Madrid and Segovia, he went to Salamanca, and duly graduated in laws. At an early age he had begun to write verses in imitation of the then much admired though now justly forgotten Eugenio Lobo; but at Salamanca he came under the influence of the purer literary taste of the elder Moratin, while to the friendship of the cultivated and well-read Caduhalso he owed his introduction to the writings of recent English poets. At the age of twenty-six Melendez obtained the prize of the Spanish Academy for the best eclogue, one of the unsuccessful competitors being the well-known Iriarte; the poem (*Batilo: egloga en alabanza de la vida del campo*, 1780) continues to be highly spoken of by native critics, who echo in various forms the remark of one of the adjudicators, that it was "redolent of the wild thyme." In 1781 Melendez went to Madrid, where Jovellanos became his friend, and obtained for him in 1783 the appointment of professor of the humanities at Salamanca. In 1784, in competition for a prize offered by the city of Madrid, he produced his longest poem, a "dramatic eclogue" entitled *Las Bodas de Camacho* ("Camacho's Wedding"), which secured the vote of the judges, but did not add to his reputation, and soon fell into neglect. His genius does not seem to have been at all dramatic; at any rate he was unfortunate in his choice of a subject so little capable of dramatic treatment as the well-known episode in *Don Quixote*. In the following year, at the age of thirty-one, he published a little volume of lyrics and pastorals which gave him the first place he still holds among Spanish poets of the 18th century. Several editions were exhausted in a single year. With poetical fame came professional advancement, and in 1789 the "Restorer of Parnassus" (Restaurador del Parnaso), as Melendez is sometimes pedantically called by his countrymen, received a judicial appointment at Saragossa, which in 1791 he exchanged for a chancery

[1] On the other hand it is not correct to appeal to the *Pœnulus* of Plautus for the epithet 'elyôn.

auditorship at Valladolid. In 1797 the publication of a new and greatly enlarged edition of his works, dedicated to the prince of the peace, was followed by his removal to Madrid to a high post in connexion with the treasury. The new poems included somewhat heavy philosophical epistles written after the manner of Young, and an unmistakably dull epic canto entitled *Cuida de Luzbel* ("The Fall of Lucifer"), suggested by Milton, as well as an *Ode to Winter*, which showed how well the author had made himself acquainted with Thomson. On the fall of his friend Jovellanos in 1798 Melendez was ordered away from Madrid, first to Medina del Campo and afterwards to Zamora, and it was not till 1802 that he was permitted to settle in Salamanca. For the next six years his literary activity was but slight, being limited to the production of a short poem on "Creation" and the preparation of an unfinished translation of the *Æneid*. After the revolution of Aranjuez (1808) Melendez accepted from King Joseph the post of councillor of state and afterwards that of minister of public instruction, a failure of patriotism which involved him in many indignities and even dangers; in 1813 he was of course compelled to quit his country, and, after sojourning successively at Alais, Nîmes, and Toulouse, he died in considerable poverty and neglect at Montpellier, on May 24, 1817. During his exile he employed himself in the preparation of a complete edition of his works, with numerous additions and corrections; this was afterwards published, along with a life of the author by Quintana, at the expense of the Government (4 vols. 8vo, Madrid, 1820; reprinted at Paris, 1832, and at Barcelona, 1838).

MELFI, a city of Italy, in the province of Potenza, 30 miles N. of Potenza, on the road and railway between that city and Foggia, is built on a small hill on the lower slopes of Monte Volture. The castle was originally erected by Robert Guiscard, but as it now stands it is mainly the work of the Doria family, who have possessed it since the time of Charles V.; and the noble cathedral which was founded in 1155 by Robert's son and successor, Roger, has had to be subjected to a modern restoration in consequence of the earthquake of 1851. In 1871 the city had 10,945 inhabitants; the commune had 9863 in 1861 and 12,657 in 1881.

Melfi is of doubtful origin, but appears to have existed at least as early as the 4th century. By the Normans it was made the capital of Apulia in 1041, and provided with fortifications. The council held by Nicholas I. in 1059, that of Urban II. in 1090, the rebellion against Roger in 1133 and the subsequent punishment, the plunder of the town by Barbarossa in 1167, the attack by Richard, count of Acerra in 1190, and the parliament of 1223, in which Frederick II. established the constitution of the kingdom of Naples, form the principal points of interest in the annals of Melfi during the more eventful period of its history. In 1348 Joanna I. of Naples bestowed the city on Niccolo Acciajuoli; but it was shortly afterwards captured, after a six months' siege, by the king of Hungary, who transferred it to Conrad the Wolf. In 1392 Goffredo Marzano was made count of Melfi; but Joanna II. granted the lordship to the Caracciolo family, and they retained it for one hundred and seven years till the time of Charles V. An obstinate resistance was offered by the city to Lautrec de Foix in 1528; and his entrance within its walls was followed by the massacre, it is said, of 18,000 of its citizens. As a bishopric Melfi is directly dependent on the Holy See.

MELITA (Μελίτη), the classical name for MALTA (*q.v.*), was also the name borne by the modern *Meleda*, one of the Dalmatian islands, situated immediately to the south of Sabbioncello and to the north of Ragusa. It is about 24 miles in length, averaging about 1½ in breadth, and has a good harbour. At one time it was supposed by some authors to have been the scene of the shipwreck of St Paul, but this point has now for some time been conclusively settled in favour of Malta. See Smith, *Voyage and Shipwreck of St Paul*, 1848.

MELITO, bishop of Sardes, a Christian writer of the 2d century, is mentioned by Eusebius (*H. E.*, iv. 21) along with Hegesippus, Dionysius of Corinth, Apollinaris of Hierapolis, Irenæus, and others, his contemporaries, as a champion of orthodoxy and upholder of apostolic tradition. Of his personal history nothing is known, and of his numerous works (which are enumerated by Eusebius) only a few fragments are now extant. They included an *Apologia* addressed to Aurelius some time between 169 and 180 A.D., two books relating to the paschal controversy, and a work entitled Ἐκλογαί (selections from the Old Testament), which contained the well-known catalogue of "the books of the Old Covenant." The fragments have been edited with valuable notes by Routh (*Reliquiæ Sacræ*, vol. i., 1814). It seems more than doubtful whether the *Apologia* of Melito "the Philosopher," discovered in a Syriac translation by Tattam, and subsequently edited by Cureton and Renan, ought to be attributed to this writer and not rather to another of the same name.

MELLONI, MACEDONIO (1798–1854), a distinguished physicist, was born at Parma on April 11, 1798. From 1824 to 1831 he was professor at Parma, but in the latter year he was compelled to escape to France, having taken part in the revolution. In 1839 he went to Naples as director of the conservatory of arts and handicrafts. He was likewise director of the Vesuvius observatory, a post which he held until 1848. Melloni received the Rumford medal of the Royal Society in 1834. In 1835 he was elected correspondent of the Paris Academy, and in 1839 a foreign member of the Royal Society. He died from an attack of cholera on August 11, 1854.

From the Royal Society catalogue of papers we find that Melloni produced eighty-six memoirs by himself, as well as three in connexion with other physicists. These embrace a wide range of subjects, but the reputation of Melloni as a physicist rests more especially upon his discoveries in radiant heat. Men of science were, in the early part of this century, very much in the dark with regard to the nature of the invisible heat rays. Leslie and others had indeed advanced the subject by means of the differential thermometer, but such an instrument was at the best a very poor substitute for the human eye. It was necessary to invent an instrument more nearly capable of doing for the dark rays what the eye does for those of light before any great increase in our knowledge of this subject could be expected to take place. This step was taken (shortly after Seebeck's discovery of thermo-electricity) in the construction of the thermo-multiplier or combination of thermopile and galvanometer which formed the subject of a joint memoir by Nobili and Melloni in 1831. In this memoir, after describing their instrument, these physicists confirmed the experiments of Leslie and others. They tried screens of glass, sulphate of lime, mica, and ice, also of water, oil, alcohol, and nitric acid enclosed in glass, and found an instantaneous effect produced in the index of their instrument except for ice and water, the source of heat being an iron ball below redness. After finding that most substances when used as screens stopped a much larger proportion of dark heat than they did of light, Melloni set himself to discover some body that might be transparent for dark heat. In this search he was rewarded with complete success. Rock-salt was found to possess this property; and he immediately proceeded to construct prisms and lenses of rock-salt with which he proved the refraction of dark heat, that is to say, of the heat proceeding from bodies below incandescence.

Melloni was likewise very successful in studying the action upon dark heat of screens of various substances. His experiments in this and other directions are described by Baden Powell in his report to the British Association on *Radiant Heat* (1840). The rays of the lamp were thrown upon screens of various materials in such a manner that the effect transmitted from all the screens was of a certain uniform amount. This constant radiation was then intercepted by a plate of alum, and it was found that very different quantities of heat were transmitted through the alum in the different cases. Melloni concludes that the calorific rays issuing from the various diaphanous screens are, therefore, of different qualities, and possess what may be termed the diathermancy peculiar to each of the substances through which they have passed. One of his screens was made of green glass, and he found that a piece of alum transmitted only 1 per cent. of the heat which had passed through this screen. Green glass and alum form, therefore, an antagonistic combination.

These experiments suggest naturally a new analogy between dark heat and light which could not fail to strike Melloni, and accordingly we soon find him describing an experiment with the solar rays transmitted through green glass and then intercepted by other

media. They pass copiously through rock-salt, he tells us, but feebly through alum, and hence Melloni concludes that there are amongst the solar rays some which resemble those of terrestrial heat, and in general that the differences observed between solar and terrestrial heat in the transmission of rays are to be attributed merely to the mixture in different proportions of these several species of rays. An instrument like the thermo-multiplier could not of course remain a monopoly, and shortly after its completion we find Professor James Forbes making use of it to prove the polarization of heat as well as to extend our knowledge of refraction. The brilliant researches of this experimentalist were, like those of Melloni, crowned with the Rumford medal of the Royal Society. On September 2, 1839, Arago communicated to the academy of sciences a letter by Melloni, who had found that rock-salt acquires by being smoked the power of transmitting most easily heat of low temperature, or dark heat. Forbes had discovered a similar property in mica split by heat, and he now showed that rock-salt roughened and mica scratched possess similar properties to blackened rock-salt. Melloni on his part took up the subject of polarization, and decided in favour of the equal polarizability of heat from different sources, a conclusion that did not then appear to Forbes to be in conformity with his experiments. It is very instructive to notice the loyalty which held both these experimentalists to the results of their observations. While Melloni differs from Forbes with regard to polarization, he will not allow the truth of a generalization proposed by Ampère, who had endeavoured to explain on the theory of undulations the identity of light and heat,—the difference of effect being dependent solely on the different wave-lengths, those producing heat being larger than those giving rise to light. Melloni admits that many phenomena may be explained by this hypothesis, but he mentions some experiments in which he thinks that this theory will not hold. The brilliant generalizer from without has of course a different point of view from the laborious experimentalist within. They are all worthy of scientific honour—for it is by the seeming conflict, but in reality the united efforts of workers such as these that the essential element of stability in the structure of scientific knowledge is finally secured.

MELON (*Cucumis Melo*, L.), a most polymorphic species of the order *Cucurbitaceæ*, the varieties of which are grouped by Naudin under ten tribes, while several other plants of less known characters probably belong to it.[1] The melon is an annual herb with palmately-lobed leaves, and bears tendrils. It is monœcious, having male and female flowers on the same plant. The flowers have deeply five-lobed campanulate corollas and three stamens. Naudin observed that in some varieties (*e.g.*, of Cantaloups) fertile stamens sometimes occur in the female flowers. It is a native of south Asia "from the foot of the Himalayas to Cape Comorin,"[2] where it grows spontaneously, but is cultivated in the temperate and warm regions of the whole world. It is excessively variable both in diversity of foliage and habit, but much more so in the fruit, which in some varieties is no larger than an olive, while in others it rivals the ponderous fruits of the gourd (*Cucurbita maxima*, L.). The fruit may be globular, ovoid, spindle-shaped, or serpent-like, netted or smooth-skinned, ribbed or furrowed, variously coloured externally, with white, green, or orange flesh when ripe, scented or scentless, sweet or insipid, bitter or even nauseous, &c. Like the gourd, the melon undergoes strange metamorphoses by crossing its varieties, though the latter preserve their characters when alone. The offspring, however, of all crossings are fertile. As remarkable cases of sudden changes produced by artificially crossing races, M. Naudin records that in 1859 the offspring of the wild melons m. sauvage de l'Inde (*C. melo agrestis*) and m. s. d'Afrique, le petit m. de Figari (*C. maculatus?*) bore quite different fruits from their parents, the former being ten to twelve times their size, ovoid, white-skinned, more or less scented, and with reddish flesh; though another individual bore fruits no larger than a nut. The offspring of m. de Figari after being crossed bore fruits of the serpent-melon. On the other hand, the serpent-melon was made to bear ovoid and reticulated fruit.[3]

With reference to the early cultivation of the melon, Naudin thinks it is probable that the culture in Asia is as ancient as that of all other alimentary vegetables. The Egyptians grew it, or at least inferior races of melon, which were either indigenous or introduced from Asia. The Romans and doubtless the Greeks were familiar with it, though some forms may have been described as cucumbers. Columella seems to refer to the serpent-melon in the phrase *ut coluber . . . ventre cubat flexo*. Pliny describes them as *pepones* (xix. 23 to xx. 6) and Columella as *melones* (xi. 2. 53); see Pickering, *Chron. Hist., of Pl.*, 229. The melon began to be extensively cultivated in France in 1629, according to Olivier de Serres. Gerard (*Herball*, 771) figured and described in 1597 several kinds of melons or pompions, but he has apparently included gourds under the same name. Pickering observes that the melon was carried by Columbus to America, and by the Portuguese to the Malayan Archipelago.

The origin of some of the chief modern races, such as "Cantaloups," "Dudaim," and probably the netted sorts, is due to Persia and the neighbouring Caucasian regions. The first of these was brought to Rome from Armenia in the 16th century, and supplies the chief sorts grown for the French markets; but many others are doubtless artificial productions of West Europe.

For cultivation of the melon, see art. HORTICULTURE, and also *Gard. Chron.*, May 6, 1882, p. 596; and for references to French literature on the same see Naudin, *ut supra*, p. 82.

MELOS (Att. Gr., Μῆλος), the modern Milo, one of the Sporades of the Ægean Sea, situated at the south-west corner of the archipelago, in 36° 45′ N. lat. and 24° 26′ E. long., 75 miles due east from the coast of Laconia. From east to west it measures about 14 miles, from north to south 8 miles, and its area is estimated at 52 square miles. The greater portion is rugged and hilly, and the culminating point, Mount Elias in the west, reaches a height of 2538 feet. Like the rest of the cluster to which it belongs, the island as a whole is of volcanic origin, with tuff, trachyte, and obsidian among its ordinary rocks. The great natural harbour, which, with a depth diminishing from 70 to 30 fathoms, strikes in from the north-west so as to cut the island into two fairly equal portions, with an isthmus not more than 1¼ miles broad, is evidently the hollow of the principal crater. In one of the caves on the south coast the heat is still so great that one cannot remain within more than a few minutes, and on the eastern shore of the harbour there is a remarkable cluster of hot sulphurous springs. Sulphur is found in abundance on the top of Mount Kalamo and elsewhere. In ancient times the alum of Milo was reckoned next to that of Egypt (Pliny, xxxv. 15 [52]), and millstones, salt (from a marsh at the east end of the harbour), and gypsum are still exported. The Melian earth (γῆ Μηλιάς), employed as a pigment by ancient artists, was probably native white-lead. Orange, olive, cypress, and arbutus trees grow throughout the island, which, however, is too dry to have any profusion of vegetation. The vine, the cotton plant, and barley are the main objects of cultivation. Including the neighbouring islands of Antimilos (4 square miles), Cimolos (16 square miles), and Polinos (5½ square miles), the total population of Melos was only 5538 in 1879.

*Antimilo*, 5½ miles north-west of Milo, is a mere uninhabited mass of trachyte, and is often called Eriomilo or Desert Melos. *Cimolos*, or *Argentiera*, less than 1 mile to the north-east, was famous in antiquity for its

[1] For generic characters see Benth. et Hook., *Gen. Pl.*, i. 826; and for a full account of the species of *Cucumis* and of the tribes of melon, by M. Naudin, see *Ann. des Sci. Nat.*, 4 sér., tom. xi. p. 34.

figs and fuller's earth (Κιμωλία γῆ), and contained a considerable city, the remains of which still cover the cliff of St Andrews. *Polinos*, *Polybos* or *Polivo*, and *Kaimeni*, or "Burned Island," the *Île Brulée* or *Isola Bruciata* of the French and Italians, lies rather more than a mile south-east of Cimolos. It was in antiquity the subject of dispute between the Melians and Cimolians. It has long been almost uninhabited.

In ancient times the city of Melos, built terrace fashion round a hill in the north-east of the main island, was a place of considerable size; "the western wall, of Cyclopean masonry, is traceable all the way down from the summit to the sea," and among the ruins are a temple in the Corinthian style and a beautiful little theatre cleared in 1836 by order of the king of Bavaria. Painted vases (the ancient Melians were great makers of this kind of ware), bronzes, gold ornaments, and similar specimens of art workmanship have been recovered from the debris; and in 1820 the "Venus of Milo," now in the Louvre, the noblest extant representation of Aphrodite, was found in the neighbourhood of the theatre. The top of the hill is now occupied by Castro, the principal village in the island. At some distance to the south-east, at the place called Tripiti (*i.e.*, τρυπητή, "the perforated"), lies a remarkable cluster of catacombs containing frescos, &c., of evidently Christian origin. Palæa Chora, about 5 miles farther south-east, is now an almost deserted village, but down to the beginning of the last century it had about 5000 inhabitants, and it continued for a time to be considered the capital of the island.

The first occupants of Melos were probably Phœnicians, but the island was Hellenized at an early date by Minyans and Dorians from Laconia. Though its inhabitants sent a contingent to the Greek fleet at Salamis, they held aloof from the Attic league, and sought to remain neutral during the Peloponnesian War. But in 416 B.C. the Athenians, having attacked the island and compelled the Melians to surrender at discretion, slew all the men capable of bearing arms, made slaves of the women and children, and introduced a body of five hundred Athenian colonists. Lysander restored the island to its old Dorian possessors, but it never recovered its former prosperity. There were many Jewish settlers in Melos in the beginning of the Christian era, and Christianity was early introduced. During the "Frankish" period the island formed part of the duchy of Naxos, except for the few years (1341–83) when it was a separate lordship under Marco Sanudo and his daughter.

MELROSE, a village of Roxburghshire, Scotland, on the south bank of the Tweed, 37 miles by rail south-south-east of Edinburgh. Its population has steadily advanced from 966 in 1851 to 1550 in 1881. Though a burgh of barony since 1609, it is a purely agricultural village, and would be of little interest but for the ruins of its abbey, now the property of the duke of Buccleuch. It was formerly called Little Fordell, and its present name even dates from the foundation of the monastery by David II. in 1136.

There had been a Columbite monastery of Melrose at the place now known as Old Melrose, about a mile and a half to the east of the village, but this establishment, probably never of much architectural magnificence, had, according to the *Chronicle of the Picts and Scots*, been destroyed by Kenneth M'Alpin in 839, and may never have recovered from the disaster. King David's abbey, which he entrusted to a body of Cistercian monks from Rievaulx (Riuall) in Yorkshire, was dedicated on Sunday 28th July 1146; it was laid in ruins by Edward II. of England in 1322; Bruce caused the work of restoration to be vigorously prosecuted, but the edifice was again burned by Richard II. in 1385. The abbey church as it now stands consequently belongs in the main to the latter half of the 14th century and the first half of the 15th, with a good many portions of a considerably later date.

Architecturally the abbey may be described as a splendid example of the Middle Pointed style, strongly affected on the one hand by Flamboyant and Perpendicular tendencies, and on the other by the individuality of some of the builders. Cruciform in plan, it measured 214½ feet from east to west, the width of the nave being 69 feet, and across the transepts 115½. The noble edifice was damaged by the English in 1545; and since the Reformation it has been altered to suit the necessities of Presbyterian worship (1618–1810), and plundered by builders to supply ornaments for houses. The whole building is now in ruins. The west end and a good part of the north side have disappeared; but the elevation of the south side is nearly entire, both the transepts and the east end are externally in very fair preservation, part of the central tower is standing, and the sculptured roof still covers the east end of the chancel. Of the individual features of the building, the great eastern window has been generally most admired since Sir Walter Scott celebrated the moonlit aspect of its "slender shafts of shapely stone." It has five lights; the height is 37 feet and the width 16; and the upper portion is filled in with delicate tracery of a geometrical design. Very beautiful too is the whole gable of the south transept. In the interior, on the north side of the nave, there still stand four of the original square piers, and one of them shows a Norman "cap." The choir, the west end of which is shut off by a massive rood-screen, has been largely "spoiled by rough 17th century work"; but enough remains of the decorative detail to provoke the admiration and despair of the modern artist in stone. The facile and at the same time elaborate rendering of vegetable forms, such as the Scotch "kail," is particularly striking. It was in the abbey-church of Melrose, where Alexander II. had long before been buried near the high altar, that the heart of Bruce found its final resting-place; and among the many tombs which afterwards gathered under the same roof were those of his faithful knight James Lord Douglas, Sir William the dark knight of Liddesdale, and the hero of Chevy Chase.

The ancient muniments of the abbacy have been preserved in the archives of the earl of Morton; they were published by the Bannatyne Club (2 vols., 1837, *Liber Sancte Marie de Melros*), under the editorship of Cosmo Innes. Among the many interesting documents is one of the very earliest specimens of the Scotch tongue. The *Chronica de Mailros*, preserved among the Cotton MSS., has been twice printed,—at Oxford (1684) by Fulman, and by the Bannatyne Club (1835), edited by John Stevenson. From about 1140 till its close in 1265 the chronicle may be considered original; it was put largely under contribution by later compilers.

Bower, *Description of the Abbeys of Melrose and Old Melrose*, Kelso, 1813; J. A. Wade, *History of St Mary's Abbey, Melrose*, Edinburgh, 1861; Fred. Pinches, *The Abbey Church of Melrose* (a series of architectural drawings), London, 1879.

MELTON MOWBRAY, a market-town of England, county of Leicester, is pleasantly situated in a fertile vale, at the confluence of the Wreake and Eye, 15 miles north-east of Leicester and 104 north of London by rail. The Eye is spanned by a bridge of four arches. The town consists principally of two main streets, and is substantially built of brick. The church of St Mary, a handsome cruciform structure partly in the Early English style, and adorned by a lofty and richly ornamented tower, was heightened, and otherwise enlarged in the reign of Elizabeth, and has also undergone modern improvements. There are largely endowed almshouses and several other charities. Melton is the seat of a celebrated hunting district, in connexion with which there are stables in the town capable of accommodating about eight hundred horses. It is also well known for its pork pies, and has a very large trade in Stilton cheese. There are breweries and tanneries, as well as an important cattle market. Ironworks have lately been erected. The town possesses great railway facilities. The population of the urban sanitary district in 1871 was 5033, and in 1881 it was 5766.

The old name of Melton was Medeltone, and the place is of considerable antiquity. During the Civil War it was in February 1644 the scene of the defeat, with great slaughter, of the parliamentary forces by the royalists. It is the birthplace of John Henley the orator.

MELUN, capital of the department of Seine-et-Marne, France, 28 miles south-east of Paris by railway, occupies a hill on the right bank of the Seine and the level ground at its foot. It owes its rank as "chef-lieu" to its central position merely; for there are two other towns in the department, Meaux and Fontainebleau, which have a larger population. Melun is near one of the most beautiful parts of the forest of Fontainebleau. Among the rich estates in its neighbourhood the most remarkable is the magnificent chateau of Vaux-Praslin, which belonged to Fouquet, superintendant of finances under Louis XIV. The church

of Notre Dame formerly belonged to a nunnery, now occupied by a central house of detention for twelve hundred prisoners. On the apse of the church of St Aspais may be seen a modern medallion in bronze, the work of the sculptor Chapu, representing Joan of Arc as the liberator of Melun. The population in 1881 was 12,145.

Melun is a very ancient town, and has played an important part in history. As early as the time of Cæsar's Gallic wars it was taken possession of by his lieutenant Labienus, in order to attack Lutetia with greater ease by the right bank of the Seine. It was pillaged by the Normans, and afterwards became the favourite residence of the first kings of the race of Capet; Robert and Philip I. both died there. During the Hundred Years' War Melun was given up by Jeanne of Navarre to her brother, Charles the Bad, but was retaken by the dauphin Charles and Duguesclin. In 1420 it made an heroic defence against Henry V. of England and his ally the duke of Burgundy. Ten years later the people of Melun, with the help of Joan of Arc, drove out the English. It was occupied by the League in 1589, and retaken by Henry IV. in the following year. Jacques Amyot was born there in 1504.

MELVILLE, Henry Dundas, Viscount (1741–1811), younger son of the Right Honourable Robert Dundas, lord president of the Scottish court of session, was born at Edinburgh in 1741, and was educated at the high school and university there. Becoming member of the faculty of advocates in 1763, he soon acquired a leading position at the bar. After his appointment as lord advocate in 1775, he gradually relinquished his legal practice to devote his attention more exclusively to public business. On entering parliament in 1774, he had joined the party of Lord North, and, notwithstanding his provincial dialect and ungraceful manner, he soon distinguished himself in the debates by his clear and argumentative speeches. After holding subordinate offices under the marquis of Lansdowne and Pitt, he in 1791 entered the cabinet as home secretary. From 1794 to 1801 he was secretary at war under Pitt, who conceived for him a special friendship. In 1802 he was elevated to the peerage as Viscount Melville and Baron Dunira. Under Pitt in 1804 he again entered office as first lord of the admiralty, when he introduced numerous improvements in the details of the department. His impeachment in 1806, for the appropriation of balances of public money remaining in his hands, resulted in his acquittal, but he never again held office. He died May 27, 1811.

MELVILLE, Andrew (1545–1622), a distinguished Scottish scholar, theologian, and religious reformer, was the youngest son of Richard Melville, proprietor of Baldovy, near Montrose, at which place Andrew was born in 1545. His father fell at the battle of Pinkie, fighting in the van of the Scottish army, two years after the birth of his son; and, his wife having soon after followed him to the grave, the young orphan, then a gentle and delicate child, was tenderly cared for by his eldest brother Richard and his amiable and pious wife, whose memory the great scholar ever afterwards cherished with the warmest gratitude and affection. At a very early age Melville began to show a strong taste for learning, and his brother did every thing in his power to give him the best education the country could then afford. The rudiments of Latin he obtained at the grammar school of Montrose, after leaving which he prosecuted the study of Greek for two years under Pierre de Marsilliers, a Frenchman whom John Erskine of Dun had induced to settle at Montrose; and such was the proficiency Melville made that on going to the university of St Andrews he excited the astonishment of both students and professors by using the Greek text of Aristotle, which no one else there understood, the Latin translation being that which was alone employed in the teaching of logic. On completing his course of study, Melville left St Andrews with the character of "the best poet, philosopher, and Grecian of any young master in the land." He then, in 1564, being nineteen years of age, set out for France to perfect his education at the university of Paris. He there applied himself especially to the study of the Oriental languages, but he had also the advantage of attending the last course of lectures delivered by Turnebus in the Greek chair, as well as those of the celebrated Ramus, whose mode of philosophizing and plan of teaching he afterwards introduced into the universities of Scotland. From Paris he proceeded to Poitiers for the purpose of studying civil law, and though only twenty-one years of age he was apparently at once made a regent in the college of St Marceon. After a residence of three years, however, the political troubles of the country compelled him to leave France, and he then went on to Geneva, where he was warmly welcomed by Theodore Beza, at whose instigation he was appointed to fill the chair of humanity in the academy of Geneva, which then happened to be vacant. In addition to his teaching, however, he also applied himself to the further prosecution of his studies in Oriental literature, and in particular acquired from Cornelius Bertram, one of his brother professors, a knowledge of Syriac. While he resided at Geneva the massacre of St Bartholomew in 1572 drove an immense number of Protestant refugees to that city, including several of the most distinguished French men of letters of the time, with whom Melville had now the opportunity of intimate intercourse. Among these were several men deeply learned in civil law and political science, and their society no doubt tended greatly both to increase Melville's knowledge of the world and to enlarge his ideas of civil and ecclesiastical liberty—acquisitions which he must have found of essential service when at a later period as a leader of the General Assembly he had to struggle against the attempts of James VI. to crush the liberties of the church of the Scottish Reformation. In 1574 Melville returned to Scotland, and almost immediately afterwards received the appointment of principal of Glasgow University, which at the time had fallen into an almost ruinous state, the college having in fact been shut up and the students dispersed. Melville, however, with the knowledge of academic methods of training which he had obtained abroad, immediately set himself with immense energy to establish a good educational system, and in a short time his fame spread through the kingdom, and students flocked in from all quarters, till the class-rooms lately empty could not contain those who came for admission. After labouring for six years in Glasgow, and having brought the seminary into a state of the most thorough efficiency, it was thought desirable that he should undertake the same duties at St Andrews. He accordingly proceeded there in 1580, and was installed as principal of the new theological college. His duties there comprehended the teaching, not only of theology, but of the Hebrew, Chaldee, Syriac, and Rabbinical languages, and the great ability of his lectures was universally acknowledged, and excited quite a new interest in the university. The sweeping reforms, however, which his new modes of teaching necessarily involved, and even some of the new doctrines which he began to introduce, such as the non-infallibility of Aristotle, soon brought him into collision with some of the other teachers in the university; and this, along with the troubles which arose from the attempts of the court to force a bastard system of Episcopacy upon the Church of Scotland, forced him to flee into England in order to escape the consequences of an absurd charge of treason which was made against him, and which seemed to threaten a prolonged imprisonment and not improbably even his life. After an absence of twenty months he returned to Scotland in November 1585, and in March 1586 resumed his lectures in St Andrews, where he continued to fulfil the duties of his office for

twenty more years. During the whole of that time, however, his more prominent work was that of contending with unwearied energy and indomitable courage against the encroachments of an unscrupulous and tyrannical Government upon the liberties of the Scottish Church. Into the details of these it is of course impossible to enter here. But that in the main he and his coadjutors were fighting for the constitutionally guaranteed rights of the church is now admitted by all candid inquirers. (See in particular *The History of England from* 1603 *to* 1616, by Samuel Rawson Gardiner, vol. i. chap. ix.). The chief charge against Melville is that his fervour often led him to forget the reverence due to an "anointed monarch." Of this, however, it is not very easy now to judge. Manners at that time were rougher than at present. Any thing more rude, insolent, and brutal than James's own occasional explosions it would be difficult to match, and a king so undignified could scarcely expect to be treated with dignity. Besides, what title had one who was acting in a purely arbitrary and illegal manner to receive other than the plainest dealing,—such as being reminded that though he was king over men he was only "God's silly vassal?" Melville's rudeness (if it is to be called so) was simply the outburst of just indignation from a brave, true, and upright man, zealous only for the purity of religion and regardless of consequences to himself, and it contrasts nobly with the grovelling sycophancy of most of the English bishops towards James. The close of Melville's career in Scotland was at length brought about by James in characteristic fashion. In 1606 he and seven other clergymen of the Church of Scotland were summoned to London in order "that his majesty might treat with them of such things as would tend to settle the peace of the church." The contention of the whole of these faithful men was that the only way to accomplish that purpose was a free Assembly. Melville delivered his opinion to that effect with his accustomed freedom and boldness, and, having shortly afterwards written a sarcastic Latin epigram on some of the superstitious practices he had observed in the chapel of Hampton Court, and some eavesdropper having conveyed the lines to the king, he was committed to the Tower, and detained there for the space of four years. On regaining his liberty, and being refused permission to return to his own country, he was invited to fill a professor's chair in the university of Sedan, and there he spent the last eleven years of his brave, active, noble, and useful life. He died at Sedan in 1622, at the age of seventy-seven.

MELVILLE, George John Whyte (1821–1878), has a right to be regarded as the founder of a school of fashionable novels,—the fashionable sporting novel. He was lamented on his death as the Tyrtæus of the hunting field, the laureate of fox-hunting; all his most popular and distinctive heroes and heroines, Digby Grand, Tilbury Nogo, the Honourable Crasher, Mr Sawyer, Kate Coventry, Mrs Lascelles, are or would be mighty hunters. The eldest son of Major Whyte Melville, of Mount Melville, Fifeshire, he received his school education, like so many of his heroes, at Eton, entered the army in 1839, became captain in the Coldstream Guards in 1846, and retired in 1849. His first appearance in literature was made soon after, with a translation of Horace into fluent and graceful verse, published in 1850. His first novel was *Digby Grand*, published in 1853. Although this first effort has a good deal more in it of Lytton's early high-flying style than Whyte Melville's later works, the unflagging verve and intimate knowledge with which he described sporting scenes and sporting characters at once drew attention to him as a novelist with a new vein. His power of sustaining interest in hunting and the things connected with hunting appeared more markedly in his next novel, *Tilbury Nogo*, contributed to the *Sporting Magazine* in 1853. He showed in the adventures of Mr Nogo, what became more apparent in his later works, that he had a surer hand in humorous narrative than in pathetic description; there are many pathetic scenes in his novels, but the pathos is sometimes rather forced, intended to point a moral—rather the pathos of the preacher than the poet. The hero of *General Bounce*, his next novel in order of publication (*Fraser's Magazine*, 1854), little as one would expect it from the title, ends in a painful manner, somewhat out of keeping with the lively middle and beginning. When the Crimean War broke out, Whyte Melville took part in it as a volunteer in the Turkish contingent; but this was the only break in his literary career from the time that he began to write novels till his death in 1878. By a strange accident, he lost his life in the hunting-field, the hero of many a stiff ride meeting his fate in galloping quietly over an ordinary ploughed field.

Twenty-one novels appeared from his pen after his return from the Crimea:—*Kate Coventry*, 1856; *The Interpreter*, 1858; *Holmby House*, 1860; *Good for Nothing*, 1861; *Market Harborough*, 1861; *The Gladiators*, 1863; *Brookes of Bridlemere*, 1864; *The Queen's Maries*, 1864; *Cerise*, 1865; *Bones and I*, 1868; *The White Rose*, 1868; *M or N*, 1869; *Contraband*, 1870; *Sarchedon*, 1871; *Satanella*, 1872; *Uncle John*, 1874; *Sister Louise*, 1875; *Katerfelto*, 1875; *Rosine*, 1876; *Roy's Wife*, 1878; *Black but Comely*, 1878. Several of these novels are historical, the *Gladiators* being perhaps the most famous of them. As an historical novelist Whyte Melville cannot be put on a level with Harrison Ainsworth for painstaking accuracy and minuteness of detail; he makes his characters live and move with great vividness, but he obviously did not know at first hand the history of the periods chosen by him. It is on his portraiture of contemporary sporting society that his reputation as a novelist must rest; and, though now and then a character reappears, such as the supercilious stud-groom, the dark and wary steeple-chaser, or the fascinating sporting widow, his variety in the invention of incidents is amazing. Whyte Melville was not merely the annalist of sporting society for his generation, but may also be fairly described as the principal moralist of that society; he exerted a considerable and a wholesome influence on the manners and morals of the gilded youth of his time. His *Songs and Verses* and his metrical *Legend of the True Cross*, though respectable in point of versification, are hardly worth mentioning on their own merits.

MELVILL VAN CARNBEE, Pieter, Baron, an eminent Dutch geographer, was born at the Hague 20th May 1816, and died October 24, 1856. He traced his descent from an old Scotch family, originally it is said of Hungarian extraction. Destined for the navy, in which his grandfather had won distinction, Melvill imbibed a taste for hydrography and cartography as a student under Pilaar in the college of Medemblik, and he showed his capacity as a surveyor on his very first voyage to the Dutch Indies (1835). In 1839 he was again in the East, and was now attached to the hydrographical bureau at Batavia. With the assistance of the long-neglected documents collected by the old company, he completed in wonderfully short time his first great hydrographical work—a map of Java in five sheets, accompanied by sailing directions (Amsterdam, 1842; 2d revised edition, 1849),—which was received with great applause. Melvill remained in India till 1845 collecting materials for his second great hydrographical work, the chart of the waters between Sumatra and Borneo (two sheets, 1845 and 1846, revised edition of first sheet 1847; compare the descriptive memoir in Tindal and

Swart's *Journal*, 1846). On his return to Holland Melvill was attached to the naval department with the special charge of studying the history of the hydrography of the Dutch Indies. He also undertook, in connexion with Von Siebold, the publication of the *Moniteur des Indes*, a valuable series of scientific papers, mainly from his own pen, on the foreign possessions of Holland, which was continued for three years. In 1850 Melvill returned to India as lieutenant of the first class and adjutant to Vice-Admiral Van den Bosch; and after the premature death of this commander he was again appointed keeper of the charts at Batavia. He was one of the founders and for a time the president of the new society for natural science (1850). In 1853 he obtained exemption from active naval service that he might devote himself to a general atlas of the Dutch Indies; and under the most unfavourable circumstances he prosecuted the task with incredible energy. But he was not to see its completion. Just after he had lost his young wife and new-born son he was called in 1856 to be director of the marine establishment of Onrust; and there he soon fell a victim to climate, dying after much suffering in the hospital of Weltevreden, only forty years of age. In spite of delays caused by the engraving of the maps in Holland, no fewer than twenty-five sheets were already finished, but it was not till 1862 that the whole plan, embracing sixty sheets, was ably brought to a close by Lieutenant-Colonel W. F. Versteeg. The premature loss of Melvill was severely felt not only in Holland but in foreign countries, where, as shown by his connexion with the geographical societies of Paris, London, Berlin, and Bergen, his labours were highly esteemed. His industry and energy were equalled only by the benevolence and warmth of his heart. In 1843 he received the decoration of the Netherlands Lion, in 1849 that of the Legion of Honour.

MEMEL, the most northerly town in Germany, and the principal seat of the Baltic timber trade, is situated in the district of Königsberg, Prussia, at the mouth of the Dange, and on the bank of a sound connecting the Kurische Haff with the Baltic Sea. On the side next the sea the town is defended by a citadel and other fortifications, and the entrance to the large and fine harbour is protected by a lighthouse. Largely rebuilt since a destructive fire in 1854, Memel contains several churches, a gymnasium, a school of navigation, an exchange, and various judicial and official establishments. It also possesses large iron-foundries, shipbuilding yards, breweries, distilleries, and manufactories of chemicals, soap, and amber wares. By far the most important interest of the town, however, is its trade, the chief items in which are timber and the grain and other agricultural products of Lithuania. The timber is brought by river from the forests of Russia, and is prepared for exportation by about thirty saw-mills. The annual value of timber exported is about £600,000. In 1880 the port of Memel was entered by 898 ships with an aggregate burden of 164,374 tons, and cleared by 932 vessels with a burden of 164,441 tons. The population of Memel in 1880 was 19,660.

Memel was founded in 1252 by Poppo von Osterna, grand master of the Teutonic order, and was at first called New Dortmund and afterwards Memmelburg. It soon acquired a considerable trade, and joined the Hanseatic League. During the 13th, 14th, and 15th centuries it was repeatedly burned down by its hostile neighbours, the Lithuanians and Poles, and in the 17th century it remained for some time in the possession of Sweden. In 1757, and again in 1813, it was occupied by Russian troops. After the battle of Jena, King Frederick William III. retired to Memel; and there, in 1807, a treaty was concluded between England and Prussia. The poet Simon Dach and the astronomer Argelander were natives of Memel.

MEMLING, Hans, a painter of the 15th century, whose art gave a passing lustre to Bruges in the period of its political and commercial decline. Though much has been written respecting the rise and fall of the school which made this city famous, it still remains a moot question whether that school ever truly existed. Like Rome or Naples, Bruges absorbed the talents which were formed and developed in humbler centres. John Van Eyck first gained repute at Ghent and the Hague before he acquired a domicile elsewhere, and Memling, we have reason to think, was a skilled artist before he settled at Bruges. Yet if the question should be asked where the manner of Memling was shaped, and where he acquired the skill which he displayed at Bruges, we shall be greatly at a loss to reply. The annals of the city are silent as to the birth and education of a painter whose name was inaccurately spelt by different authors, and whose identity was lost under the various appellations of Hans and Hausse, or Hemling and Memling. But no other city of the Netherlands has vindicated the right which Bruges had no means of proving. Travellers who came to Bruges were only told that Memling's masterpieces were preserved in the hospital of St John. In one of these pictures it was said a portrait of the artist might be discovered; on the sculptured ornaments of a porch enframing one of its subjects an incident of the master's life might be traced,—his danger as he lay senseless in the street, his rescue as charitable people carried his body to the hospital. The legend grew too. It came to be told how the great artist began life as a soldier who went to the wars under Charles the Bold, and came back riddled with wounds from the field of Nancy. Wandering homeward in a disabled state in 1477, he fainted in the streets of Bruges, and was cured by the Hospitallers. Unknown to them, and a stranger to Bruges, he gave tangible proofs of his skill to the brethren of St John, and showed his gratitude by refusing payment for a picture he had painted. Unhappily the legend refutes itself. The portrait of Memling is a myth; the carvings of the capitals of the porch represent the ordinary incidents attending the reception of patients at an hospital. Memling did indeed paint for the Hospitallers, but he painted not one but many pictures, and he did so in 1479 and 1480, being probably known to his patrons of St John by many masterpieces even before the battle of Nancy.

Memling is only connected with military operations in a mediate and distant sense. His name appears on a list of subscribers to the loan which was raised by Maximilian of Austria to push hostilities against France in the year 1480. When he signed this list his position was that of a resident at Bruges who had probably lived there long enough to acquire a large practice and its advantages in the form of lands and tenements. In 1477, when he is said to have fallen, and when Charles the Bold was killed, he was under contract to furnish an altarpiece for the guild chapel of the booksellers of Bruges; and this altarpiece, now preserved, under the name of the Seven Griefs of Mary, in the gallery of Turin, is one of the fine creations of his riper age, and not inferior in any way to those of 1479 in the hospital of St John, which for their part are hardly less interesting as illustrative of the master's power than the Last Judgment in the cathedral of Dantzic. Critical opinion has been unanimous in assigning the altarpiece of Dantzic to Memling, and by this it affirms that Memling was a resident and a skilled artist at Bruges in 1473; for there is no doubt that the Last Judgment was painted and sold to a merchant at Bruges, who shipped it there on board of a vessel bound to the Mediterranean, which was captured by a Dantzic privateer in that very year. But, in order that Memling's repute should be so fair as to make his pictures purchasable, as this had been, by an agent of the Medici at Bruges, it is incumbent on us to acknowledge that he had furnished sufficient proofs before that time of the skill which excited the wonder of such highly cultivated

patrons; and thus we come to admit without much difficulty the possible truth of a report made by a chronicler of the 16th century that Memling had sittings from Isabella, consort of Philip the Good of Burgundy, in the year 1450.

It is characteristic that the very oldest allusions to pictures connected with Memling's name are those which point to relations with the Burgundian court. The inventories of Margaret of Austria, drawn up in 1524, allude to a triptych of the God of Pity by Roger van der Weyden, of which the wings containing angels were by "Master Hans." But this entry is less important as affording testimony in favour of the preservation of Memling's work than as showing his connexion with an older Flemish craftsman. For ages Roger van der Weyden was acknowledged as an artist of the school of Bruges, until records of undisputed authenticity demonstrated that he was bred at Tournai and settled at Brussels. Nothing seems more natural than the conjunction of his name with that of Memling as the author of an altarpiece, since, though Memling's youth remains obscure, it is clear from the style of his manhood that he was taught in the painting-room of Van der Weyden. Nor is it beyond the limits of probability that it was Van der Weyden who received commissions at a distance from Brussels, and first took his pupil to Bruges, where he afterwards dwelt. The clearest evidence of the connexion of the two masters is that afforded by pictures, and particularly an altarpiece, which has alternately been assigned to each of them, and which may possibly be due to the joint labours of both. In this altarpiece, which is a triptych ordered for a patron of the house of Sforza, we find the style of Van der Weyden in the central panel of the Crucifixion, and that of Memling in the episodes on the wings. Yet the whole piece was assigned to the former in the Zambeccari collection at Bologna, whilst it was attributed to the latter at the Middleton sale in London in 1872. At first, we may think, a closer resemblance might be traced between the two artists than that disclosed in later works of Memling, but the delicate organization of the younger painter, perhaps also a milder appreciation of the duties of a Christian artist, may have led Memling to realize a sweet and perfect ideal, without losing, on that account, the feeling of his master. He certainly exchanged the asceticism of Van der Weyden for a sentiment of less energetic concentration. He softened his teacher's asperities and bitter hardness of expression.

In the very oldest form in which Memling's style is displayed, or rather in that example which represents the Baptist in the gallery of Munich, we are supposed to contemplate an effort of the year 1470. The finish of this piece is scarcely surpassed, though the subject is more important, by that of the Last Judgment of Dantzic. But the latter is more interesting than the former because it tells how Memling, long after Roger's death and his own settlement at Bruges, preserved the traditions of sacred art which had been applied in the first part of the century by Roger van der Weyden to the Last Judgment of Beaune. All that Memling did was to purge his master's manner of excessive stringency, and add to his other qualities a velvet softness of pigment, a delicate transparence of colours and yielding grace of slender forms. That such a beautiful work as the Last Judgment of Dantzic should have been bought for the Italian market is not surprising when we recollect that picture-fanciers in that country were familiar with the beauties of Memling's compositions as shown in the preference given to them by such purchasers as Cardinal Grimari and Cardinal Bembo at Venice, and the heads of the house of Medici at Florence. But Memling's reputation was not confined to Italy or Flanders. The Madonna and Saints which so lately passed out of the Duchatel collection into the gallery of the Louvre, the Virgin and Child of Sir John Donne at Chiswick, and other noble specimens in English and Continental private houses show that his work was as widely known and appreciated as it could be in the state of civilization of the 16th century. It was perhaps not their sole attraction that they gave the most tender and delicate possible impersonations of the "Mother of Christ" that could suit the taste of that age in any European country. But the portraits of the donors with which they were mostly combined were more characteristic, and probably more remarkable as likenesses than any that Memling's contemporaries could produce. Nor is it unreasonable to think that his success as a portrait painter, which is manifested in isolated busts as well as in altarpieces, was of a kind to react with effect on the Venetian school, which undoubtedly was affected by the partiality of Antonello da Messina for trans-Alpine types studied in Flanders in Memling's time. The portraits of Sir John Donne and his wife and children in the Chiswick altarpiece are not less remarkable as models of drawing and finish than as refined presentations of persons of distinction; nor is any difference in this respect to be found in the splendid groups of father, mother, and children which fill the noble altarpiece of the Louvre. As single portraits, the busts of Burgomaster Moreel and his wife in the museum of Brussels, and their daughter the Sibyl Zambetha in the hospital of Bruges, are the finest and most interesting of specimens. The Seven Griefs of Mary in the gallery of Turin, to which we may add the Seven Joys of Mary in the Pinakothek of Munich, are illustrations of the habit which clung to the art of Flanders, of representing a cycle of subjects on the different planes of a single picture, where a wide expanse of ground is covered with incidents from the Passion in the form common to the action of sacred plays. The time came, no doubt, when the players took their cue from the painters, as in the Ghent procession, which was formed on the model of Van Eyck's Adoration of the Lamb. But in Memling's days there were still some original "players," and the public was not averse to seeing illustrations of their work. In the first period of the development of Belgian art too, when the Flemings assigned more importance to carved work than to painting, and yet refused to accept sculpture without colour, it was natural that the sculptor should multiply incidents on bas-reliefs which were coated with tinting in the semblance of nature. Memling's pictures imitate reliefs so far as they abound in variety of episodes, and are marked by absence of contrast in light and shade or want of toning by gradations of atmosphere. Yet with all these peculiarities his works are very pleasant to the eye, because they are always graceful and quiet.

The masterpiece of Memling's later years, a shrine containing relics of St Ursula in the hospital of Bruges, is fairly supposed to have been ordered and finished in 1480 after the painter had become acquainted with the scenery of the Rhine. This shrine is one of the most interesting monuments of mediæval art in Flanders, not only because it is beautifully executed, but because it reveals some part of the life of the painter who produced it, and illustrates the picturesque legend of Ursula and her comrades. The delicacy of finish in its miniature figures, the variety of its landscapes and costume, the marvellous patience with which its details are given, are all matters of enjoyment to the spectator. There is later work of the master in the St Christopher and Saints of 1484 in the academy, or the Newenhoven Madonna in the hospital of Bruges, or a large Crucifixion with scenes from the Passion, of 1491, in the cathedral of Lübeck. But as we near the close of Memling's career we observe that his practice has become larger than he can compass alone; and, as usual in such cases, the labour of disciples is substituted for his own. The registers of the painters' corporation at Bruges give the names of two apprentices who served their time with Memling and paid dues on admission to the guild in 1480 and 1486. These subordinates remained obscure.

It would be easy to form a long list of pictures by Memling in the galleries of Berlin, Florence, London, Madrid, Paris, Rome, and Vienna, and pieces equally remarkable in many private collections of England and the Continent. These have all been described, and are widely known. The present notice must be closed with the admission that pictures tell more of Memling's life than records. The date of the master's death is not better certified than that of his birth. This much, however, is certain. The trustees of Memling's will appeared before the court of wards at Bruges on the 10th of December 1495, and we gather from records of that date and place that Memling died a short time before, leaving behind several children and a considerable property. (J. A. C.)

MEMMI. See MARTINI, SIMONE.

MEMMINGEN, a town of Bavaria, in the district of Schwaben and Neuburg, is situated about 35 miles to the south-west of Augsburg, near the river Iller. It is a well-built town, still partly surrounded with walls, and contains a Roman Catholic and three Protestant churches, a town-house of 1580, and several schools and charitable institutions. Its industrial products are yarn, calico, woollen goods, and thread. A considerable trade is carried on in hops, which are extensively cultivated in the neighbourhood, and in wool, leather, and grain. The population in 1880 was 8050.

Memmingen, first mentioned in a document of 1010, belonged originally to the Guelph family. In 1286 it became a free city of the empire, a position which it maintained down to 1802, when it was allotted to Bavaria. In 1529 Memmingen was one of the "pro-

testing" towns represented at the diet of Spires. During the Thirty Years' War it was alternately occupied by Swedes and Imperialists. In 1800 the French under Moreau gained a victory over the Austrians near Memmingen. Compare Dobel, *Memmingen im Reformationszeitalter*, 1877–78.

MEMNON. In the Homeric mythology (or rather the mythology of the *Troica* in the much fuller form in which it existed in the times of Pindar and the tragic poets) this hero was called the son of Tithonus (the half-brother of Priam) and Eos (Aurora). Tradition represented him as an Ethiopian prince who came to assist the Trojans against the Greeks, and performed prodigies of valour, but was at length killed by Achilles, after having himself slain Antilochus, the son of Nestor, an event alluded to in Pindar, *Pyth.*, vi. 32–39. His story must have been very famous, for more than one Greek play was composed bearing the title.

The chief source from which our knowledge about Memnon as a chief is derived is the second book of the *Post-Homerica*, by Quintus Smyrnæus, where his exploits and death are described at length. That Memnon was slain by Achilles is more than once affirmed by Pindar (*Nem.*, vi. 52; *Isthm.*, iv. 41, vii. 54). He is mentioned also in the *Odyssey* (xi. 522), with especial praise for personal beauty; but the allusion to him is quite casual, and is one of many proofs that the compilation of that and the sister epic presupposes in the reader or hearer a full knowledge of the whole tale of Troy. Modern philology associates Memnon—like Achilles, whom he so closely resembles in many particulars, and like Sarpedon, who seems the representative of Memnon in the Iliad—with solar phenomena. He was the son of the dawn, and, though he might vanish from sight for a time, he could not be destroyed, and therefore it was said that Zeus, moved by the tears of his mother, granted him immortality. In this respect, as also in wearing bright armour made by Hephæstus, he is the counterpart of Achilles, who symbolizes the mid-day sun in his glory; and that Memnon is said to have come from the far east, *i.e.*, from the region of sunrise, is in itself significant. Ovid, in a beautiful elegy on the death of Tibullus, *Amor.*, lib. iii. 9, 3, thus associates the fates of Memnon and Achilles:—

> Memnona si mater, mater ploravit Achillen,
> Et tangunt magnas tristia fata deas,
> Flebilis indignos, Elegeia, solve capillos;
> Ah nimis ex vero nunc tibi nomen erit.

Like the body of the dead hero Sarpedon (*Il.*, xvi. 681), so that of Memnon was borne through the air, a legend represented on Greek vases of a rather early date. This appears to mean that the sun, the offspring of the dawn, careers through the sky to the place of his departure in the west. Another account represents Zeus as having sent forth birds from the funeral-pile of Memnon, which straightway fought with each other, and many fell back as victims to the soul of the hero.

The mere fact that a *Memnonium*, or temple in honour of the hero, was erected both at Susa and at Egyptian Thebes, both of which places were centres of sun-worship, is a strong confirmation of the probability, derived from his mythical pedigree, that he was really a sun-god. Sir G. W. Cox remarks,[1] "of Memnon's head the story was told that it retained the prophetic power of the living Helios or of Surya. The story is found in the myth of the Teutonic Wismir, and it might have been related of Kephalos, the head of the sun;" and again (p. 267), "Eos, the mother of Memnon, is so transparently the morning that her child must rise again as surely as the sun reappears to run his daily course across the heaven."

With respect to the meaning of the name, it may possibly be the same as Agamemnon, which has a prefix meaning *brave*.[2] It has been thought that Μέμνων and *μνήμων*, "mindful," are but forms of the same word, and that the prophetic power attributed to the head of the Egyptian Memnon, which was said to utter sounds at sunrise, is connected with this idea. It was said that the sound resembled the moaning noise or the sharp twang of a harp-string, and it may even be surmised that the syllables *mem-non* imitated the resonance. The Egyptian head is said to be a bust of King Amenophis;[3] but if the Greeks fancied it uttered the word *memnon*, they would have called it by that name. The tendency, however, to give a Greek shape and inflexion to words which sounded barbarous will sufficiently account for the misnaming of the statue.

Strabo, lib. xvii. p. 816, declares that he himself heard it in company with Ælius Gallus and several of his friends, and Pausanias (i. 42, 2) says "one would compare the sound most nearly to the broken chord of a harp or a lute." See also Juv., *Sat.*, xv. 5; Tac., *Ann.*, ii. 61.

Memnon, as an Ethiopian, was of course represented as a black; hence Virgil (*Æn.*, i. 493) speaks of "nigri Memnonis arma." The figure itself was cut out of black basalt, but that is a material not uncommon in Egypt. Speaking quite generally, it seems reasonable to conclude that the Memnon from Ethiopia (which the early Greeks placed in the far east rather than in the south) typifies the eastern sun summoned to oppose the enemies of darkness from the west.

MEMPHIS, the capital of the old Egyptian empire, founded by Menes, the first historical king; see vol. vii. pp. 731, 770. In the time of Strabo (xvii. p. 807) it was the second city of Egypt, inferior only to Alexandria, and with a mixed population like the latter. Memphis was still an important though declining place at the time of the Moslem conquest. Its final fall was due to the rise of the Arabic city of Fosṭáṭ on the right bank of the Nile almost opposite the northern end of the old capital; and its ruins, so far as they still lay above ground, gradually disappeared, being used as a quarry for the new city. The remains of "Menf" were still imposing late in the 12th century, when they were described by 'Abd el-Laṭíf. In the Old Testament Memphis is mentioned under the names of Moph (Hos. ix. 6) and Noph (Isa. xix. 13; Jer. ii. 16; Ezek. xxx. 13, 16).

MEMPHIS, a city of the United States, and port of entry, capital of Shelby county, Tennessee, is situated on the east bank of the Mississippi river just below the mouth of Wolf river, in about 35° 8′ N. lat. and 90° 5′ W. long., 450 miles below St Louis and 826 miles above New Orleans. The bluff on which the city stands has an average elevation of 47½ feet above high-water mark, with a further fall of 36 feet to extreme low water. Memphis is methodically and tastefully planned, and is adorned with many elegant private residences and public buildings, conspicuous among the latter being the United States custom house, located upon the esplanade between Front Street and the river, and built of the best quality of marble, the product of Tennessee quarries. A small park in the centre of the city contains a bust of Andrew Jackson. The streets are mostly well-paved, and are supplied with water from the Wolf river by the Holly system. The bayou Gayoso, with several branches, intersects the city, and prior to 1880 received most of its drainage. Since that date over 40 miles of sewers and more than that length of subsoil drain-tiles have been constructed on the Waring system, providing the city with a superior system of drainage.

[3] Φαμένωφ, as the Thebans themselves said, according to Pausanias, cited below.

Memphis is the largest city of the State, and the most important commercial city on the Mississippi between St Louis and New Orleans. The largest sea-going vessels ascend the river to this point, and navigation is open at all seasons of the year. The city also possesses abundant facilities for transportation by railway in every direction. Memphis ranks as the largest interior cotton-market in the United States. The receipts for the season ending September 1, 1881, were 470,267 bales, with a value of $23,090,109. The aggregate receipts from the mercantile and manufacturing interests for the year ending September 1, 1882, amounted to about $60,000,000, of which the trade in groceries and western products contributed nearly $40,000,000; dry goods, clothing, boots and shoes, and general merchandise $15,000,000; and various home manufactures about $5,000,000. There are oil-mills and refineries, whose annual product of about 30,000 barrels of cotton-seed oil, together with oil-cake and re-ginned cotton, amounts to over $1,000,000. There are also numerous foundries, machine shops, flouring-mills, and manufactories of carriages, furniture, and tobacco.

The city contains, besides the usual religious, educational and commercial institutions, a public library of 9000 volumes, three daily and ten weekly newspapers, a chamber of commerce, and a cotton exchange.

Memphis was laid out as a village in 1820, and incorporated as a city in 1831. Its population at each census since has been as follows:—3360 in 1840, 8841 in 1850, 22,623 in 1860, 40,226 in 1870, and 33,592 in 1880. According to a census taken on October 1, 1882, the population within the city limits was 47,976 (29,130 white and 18,846 coloured).

During the civil war Memphis was early occupied by the Union forces (June 6, 1862) after a naval engagement in which Commodore Davis with a fleet of nine gunboats and rams defeated a similar Confederate fleet of eight vessels, and captured or destroyed all of them but one. The city was held by Federal troops to the close of the war, with the exception of a brief occupation, in August 1864, by General Forrest, who captured several hundred prisoners, but immediately withdrew. The decrease of population between 1870 and 1880 was due to the ravages of yellow fever in 1873, 1878, and 1879. The epidemic of 1873 resulted in over two thousand deaths. In 1878, according to the report of the Howard Relief Association, the number of those attacked with the fever was 15,000, and the number of deaths reached the total of 5150, of whom 4250 were whites and 900 coloured. At the return of the fever in 1879 better care and strict quarantine arrangements prevailed, but there were 1595 cases, with 497 deaths. During the epidemics of 1878 and 1879 fully two-thirds of the population fled from the city, many of whom died of the fever at other places, and a still larger number did not return. For three months during each year business was wholly suspended, and all ingress or egress except for the most necessary purposes was forbidden. The prostration of the business of the place left the city almost hopelessly bankrupt, and as a means of relief the legislature of the State in January 1879 repealed the city's charter, and, assuming exclusive control of its taxation and finances, constituted it simply a "taxing district," placing its government in the hands of a "legislative council." This anomalous proceeding has been declared constitutional by the supreme court of Tennessee. Under it Memphis is at least regaining its prosperity, and by thoroughly cleansing, repaving, and sewering its streets, and supervising the construction of buildings, is likely to become one of the healthiest cities on the Mississippi river.

## LONGSTREET—LORIMER

LONGSTREET, James, was born in South Carolina, Jan. 8, 1821. He graduated at the military academy at West Point in 1842, and was on duty on the Mexican frontier till 1846; took part in the Mexican war, 1846–48, where he was wounded; served as paymaster in the United States army, being promoted major on the staff in 1858. He resigned his commission to take part with the South in the civil war; was present at the battle of Bull Run. During the early part of 1862 he was made major-general, and won reputation under General Lee in the campaigns against McClellan, Pope, Burnside, and Meade. After the battle of Fredericksburg, Longstreet was promoted to the command of a corps, with the rank of lieutenant-general. He took an active part in the battle of Gettysburg. He was also conspicuous for his military ability in the campaign of the Wilderness, and was severely wounded, but recovered in time to take command of his corps during the siege of Petersburg. He surrendered with General Lee in April, 1865. After the war General Longstreet acted zealously for the restoration of harmony between the two sections. He made New Orleans his residence, and, having been amnestied by President Johnson, he was so cordial toward the administration that President Grant appointed him surveyor of the port of New Orleans. In 1875 he took up his residence in Georgia, and in 1880 was sent as minister to Turkey, where he remained until 1881. He was subsequently United States marshal for the northern District of Georgia, but at present holds no official position.

LONGVIEW, a post-village, a railroad junction and the county-seat of Gregg county, Texas, on Sabine River. There is an abundance of lumber in the vicinity and forty saw-mills are employed in its manufacture. Pop. (1890), 2,034.

LÖNNROT, Elias, a Finnish philologist, born at Sammatti, near Helsingfors, in 1802, died in 1884. After obtaining the degree of M.D. at the University of Helsingfors in 1832 and practicing as a physician at Kajana, he was in 1853 made professor of the Finnish language and literature at the University of Helsingfors, he having for years collected Finnish songs, proverbs and tales, and studied the Finnish language thoroughly. His master work is the *Kalewala*, a national epic, imitated by Longfellow in his *Hiawatha*.

LOOMIS, Elias (1811–1889), an American physicist. From 1833 to 1836 he was a tutor at Yale College, and from 1837 to 1844 was professor of mathematics and natural philosophy in Western Reserve College, Ohio. He then became professor of natural philosophy in the University of the City of New York, holding the office until 1860, when he accepted a call to the chair of natural philosophy and astronomy in Yale. He published a series of text books embracing the whole range of mathematics, natural philosophy, astronomy and meteorology. His *Treatise on Analytical Geometry and Calculus* has been translated into the Chinese language, and his *Treatise on Meteorology* into Arabic. His scientific papers embrace the various departments of meteorology, the phenomena of auroral exhibitions and atmospheric electricity, territorial magnetism, astronomical observations, shooting-stars, solar spots, etc. Professor Loomis was a member of the principal scientific societies of the United States and also of several scientific academies of Europe.

LOPEZ, Narciso (1799–1851), a Spanish-American soldier. At the beginning of the war for the independence of Venezuela he took the popular side, but soon afterward entered the Spanish army and at the close had gained the rank of colonel. He then went to Spain, and served in the first Carlist war. In 1839 he was made major-general, and was appointed governor of Valencia. In 1843 he retired to private life in Cuba, and in 1848 joined the revolutionary party. On account of the discovery of a conspiracy against the government in which he was interested, Lopez fled the following year to New York. He afterwards led three filibustering expeditions from the United States to Cuba, but was captured and executed by the garrote.

LORAIN, a post-village and railroad junction of Lorain county, Ohio, twenty-six miles west of Cleveland. It has car-shops, churches, a graded school, and planing-mills. Pop. (1890), 4,868.

LORAIN, Lorenzo, born in Pennsylvania, Aug. 3, 1831; died in Baltimore, March 6, 1882. He graduated at West Point in 1856, and served on the frontier. He was wounded in the early part of the civil war, and retired from active service to become professor of geology and chemistry at West Point. In 1875 he held the chair of physics at Lehigh University, and was afterward instructor in gunnery at Fortress Monroe.

LORD-LIEUTENANT of IRELAND, the viceroy or deputy of the sovereign to whom the government of Ireland is nominally committed. The office has existed from a remote period, the appointment having been made under different designations. The lord-lieutenant is appointed under the great seal of the United Kingdom, and bears the sword of state as the symbol of his viceregal office. In recent years the position of the lord-lieutenant has become little more than an "ornamental" one; but Mr. Gladstone, in his Home Rule bill, proposes to strengthen the office.

LORELEI, a cliff on the right bank of the Rhine, near St. Goar. It rises perpendicularly to a height of 427 feet, and is penetrated by a railway tunnel. Here is the famous echo renowned through Heine's song based on the tradition of the cave in the rock, the abode of the Lorelei, a wicked siren, whose song and beauty allured boatmen into a whirlpool at the base of the rock.

LORIMER, James, M.A., LL.D., professor of public law in the University of Edinburgh, was born at Aberdalgie, near Perth, Scotland, Nov. 4, 1818. Mr. Lorimer was educated at the university of Edinburgh, and subsequently studied at th

academy of Geneva and at the universities of Berlin and Bonn. In 1845 he became a member of the Scotch bar, and in 1862 professor of public law. He was one of the founders of the institute of international law, 1873; and with its members and earlier continental friends has always maintained intimate relations. He is a member of the academy of jurisprudence of Madrid, and of the universities of St. Petersburg and Moscow, a fellow of the Royal Society of Edinburgh, etc.

LORING, GEORGE BAILEY, born in Massachusetts, Nov. 8, 1817. Educated at Harvard, in 1843–50 he was surgeon to the Marine hospital at Chelsea. In 1849 he was appointed on a commission to revise the system of the U. S. Marine hospital. For many years he devoted himself to the study of theoretical and practical agriculture and wrote many papers thereon. He was U. S. Centennial Commissioner, 1872–76; from 1873 to 1877 was president of the State Senate of Massachusetts; was member of Congress, 1876–81; and 1881–85 was commissioner of agriculture. In 1889 he was appointed Minister to Portugal, which office he resigned in 1890. He died Sept. 14, 1891.

LORING, WILLIAM WING (1818–1886), an American soldier. At thirteen he enlisted in a company of volunteers to fight the Seminole Indians of Florida, and gained a second lieutenancy. In 1842 he was admitted to the bar, and shortly afterward was chosen to the Florida legislature. At the beginning of the Mexican war he was made captain in a regiment of mounted riflemen, and at the close had become a lieutenant-colonel. Some time afterward he was ordered to Texas, where he remained till 1856, acquiring the rank of colonel, and then was engaged against hostile Indians in New Mexico. In 1861 he resigned his commission and entered the Confederate army as brigadier-general. He fought with distinction in several important battles, and attained the rank of major-general. In 1869 he accepted the post of liwa pacha in the army of the Khedive of Egypt, and in 1876 was promoted to ferik, or general of division, and decorated by the Khedive with the imperial order of the Osmanleh. He returned to the United States in 1879. Gen. Loring published *A Confederate Soldier in Egypt* (1883).

LORNE, JOHN GEORGE EDWARD HENRY DOUGLAS SUTHERLAND CAMPBELL, MARQUIS OF, a governor-general of Canada, born in London in 1845. In 1866 he became captain of the London Scottish volunteers, and two years later was promoted lieutenant-colonel of the Argyle and Bute volunteer artillery brigade, about the same time being chosen a member of Parliament. In 1871 he married Princess Louise Caroline Alberta, sixth child of Queen Victoria, and in 1878 was appointed governor-general of Canada. His term of office expired in 1883. The Marquis of Lorne has written for magazines, and is the author of several books, including the Psalms in verse.

LOS ANGELES, a city of California, the chief town and business center of the southern part of the State. It was incorporated as a city in 1850. It is noted for its orange groves and vineyards, and is now a favorite winter resort for eastern tourists. The climate is delightful. Los Angeles is on the Southern Pacific Railroad and at the junction of four branch railroads. It is the seat of the Branch Normal School of the State, and of the Medical School of the University of Southern California. The city has a large trade in oranges, wines, raisins, and other southern fruits. Its leading manufacture is that of large water-pipes for irrigation works. Population in 1890, 50,394. See Britannica, Vol. XV. D. 7.

LOSSING, BENSON JOHN (1813–1891), an American author. For a time he was a watchmaker in Poughkeepsie, and then became a proprietor and editor of the Poughkeepsie "Telegraph." In 1836 he began the publication called the "Poughkeepsie Casket," and later became a wood engraver in New York city. He wrote a large number of popular historical and biographical works. Besides these, he contributed to "Harper's Magazine" and other periodicals a number of papers, and was a very industrious collector of documents relating to American history. He died June 5, 1891.

LOT, one of the largest tributaries of the Garonne in France. It rises in a section of the Cevennes, flows in a western direction, at first as the Olt, and joins the Garonne at Aiguillon, after a course of nearly three hundred miles, almost two-thirds of which is navigable.

LOTHROP, GEORGE VAN NESS, was born in Massachusetts, Aug. 8, 1817. Graduated from Brown, and educated for the bar, Mr. Lothrop began the practice of law in Detroit, Mich., in the spring of 1844. Attorney-general of Michigan in 1848–51 and recorder of the city of Detroit for two years; as a member of the convention, he supported the nomination of Stephen A. Douglas in 1860. He was a member of the constitutional convention in 1867. In 1885 Mr. Lothrop was appointed minister plenipotentiary to Russia.

LOTHROP, HARRIET MULFORD, born in Connecticut, June 22, 1844. Educated near home, she traveled widely through the United States and early entered upon a literary life, though she published nothing before 1877, when her short stories and sketches began to appear in the periodicals. Her books and magazine sketches have all appeared under her *nom de plume*, "Margaret Sidney." Since 1881, she has published several books.

LOTOPHAGI (Gr. "*lotus eaters*"), a name applied to a peaceful and hospitable people inhabiting a district of Cyrenaica, on the north coast of Africa, and much depending for their subsistence on the fruit of the lotus tree. According to Homer they received Ulysses hospitably when in the course of his wanderings he visited them with his companions, on whom, however, the sweetness of the lotus fruit had such an influence that they forgot their native country and had no desire to return home.

LOTTERIES. By law of Congress it is forbidden to use the United States mail for the purpose of forwarding lottery tickets and circulating advertisements of lotteries. In twenty-nine States of our Union the constitutions forbid lotteries, and the statute laws of all the States, including Louisiana, are against these schemes. Yet lotteries exist in our large cities, are carried on clandestinely, are a continuous temptation to the weak, and are very demoralizing in their effect. The New York Society for the Suppression of Vice has for the past five years done all in its power to bring the so-called "policy-shops" to light and to suppress them. See Britannica, Vol. XV, p. 11.

LOTUS, a genus of leguminous plants similar to the clovers. The most common species, *Lotus corniculatus*, is known in Great Britain as bird's-foot trefoil, and is a valuable addition to pasture grasses. The lotus of Barbary, described by Homer in Odys. IX, 84, and Herodotus, IV, 177, when they speak of the *Lotophagi* (lotus-eaters), is a prickly shrub, the jujube tree (*Zizyphus lotus*) whose fruit tastes sweet, like dates. It still grows in abundance and is much used as food. The sailors of Ulysses are said to have lost all desire of returning home after eating this fruit. The white and blue water-lilies of the Nile, *Nymphæa cærulea* and *N.*

*lotus* have also been given the name lotus. They were worshipped by the ancient Egyptians. The "lotus flower" of India is *Nelumbium speciosum*, another sacred water-lily, growing in Egypt, China and India. Its seeds and roots are eaten. A closely similar American species, *N. luteum*, known as the "water chinquapin," has been called lotus by American writers, but without scientific warrant.

LOUDOUN, John Campbell, Earl of, born in Scotland in 1705; died there April 27, 1782. He succeeded to the chief command of the British forces in North America, with the added honorary distinction of nominal governor of Virginia. In 1756 he came to Virginia. He imposed an embargo on commerce, impressed 400 men in New York into government service, and, after committing other arbitrary acts, went to Halifax, Nova Scotia, where he had an army of 10,000 men, and a fleet of sixteen vessels. Although the French were gaining ground in all directions, such was the irresolution and incapability of the British commander that he made no attempts, either by sea or land, to counteract or stay the French encroachments.

LOUDON, John Claudius, a Scotch writer and horticulturist, born at Cambuslang, near Glasgow, in 1783, died at London in 1843. He went in 1803 to London, where he became a landscape-gardener. In 1819 he began to publish his encyclopædias. The first one was *Encyclopædia of Gardening* (1822); then came the *Encyclopædia of Agriculture;* the *Encyclopædia of Plants;* the *Encyclopædia of Cottage, Garden, and Villa Architecture* (1832). His *Arboretum et Fruticetum* (1838), being an account of all the trees and shrubs of Great Britain, was too costly for him to publish. In his later years he lost the use of his hands, but he continued to conduct several magazines on landscape-gardening.

LOUDONVILLE, a post-village of Ashland county, Ohio, on the Black Fork of the Mohican River, and on a railroad. It has a school, churches, tannery, mills, and a population of 1,444.

LOUIS I., late King of Portugal, second son of Donna Maria II., Queen of Portugal, and Dom Fernando, Prince of Saxe-Coburg, born October, 1838; succeeded to the throne on the death of his brother, King Pedro V., Nov. 11, 1861. He married, Oct. 6, 1862, Pia, youngest daughter of Victor Emmanuel, King of Italy, by whom he had two sons: Carlos, born Sept. 28, 1863, and Alfonso, born July 31, 1865. He published in 1877 a translation into Portuguese of Shakespeare's *Hamlet*. It was followed in 1880 by a translation of the *Merchant of Venice*. In that year also he completed his translation into Portuguese of Shakespeare's *Richard III*. A second edition of the King's translation of *Hamlet* was issued in 1880. The first edition was limited to 1,000 copies. King Louis died at Lisbon, Oct. 18, 1889.

LOUIS IV. (Frederick William Louis Charles), K.G., Grand Duke of Hesse-Darmstadt, eldest son of Prince Charles William Louis of Hesse-Darmstadt, born Sept. 12, 1837, is a captain in the first regiment of the Prussian guard, and colonel of a regiment of hussars. He married the Princess Alice, second daughter of Queen Victoria, July 1, 1862. He succeeded to the grand-dukedom on the death of his uncle, Louis III., June 13, 1877, and was left a widower on Dec. 14, 1878. Some years later he morganatically married Madame de Kolomine, but after a short time divorced her. He died March 13, 1892, and was succeeded by his son, Louis V., born Nov. 25, 1868.

LOUISBURG, a small village on the southeast coast of Cape Breton Island, in Nova Scotia. Its excellent harbor induced the French, who originally inhabited the place, to build a very strong fortress here, at an expense of thirty million francs. During the war between France and England, which broke out in 1744, the New England colonists attacked this place, as it menaced their fisheries by sheltering French privateers. The New Englanders, 4,000 strong, besieged Louisburg, and the garrison, 1,600 strong, had to surrender, June 28, 1745. By the peace of Aix-la-Chapelle, in 1748, the town was again restored to France.

In 1758 a British general, Wolfe, the subsequent hero of Quebec, besieged Louisburg, and compelled the French garrison to surrender as prisoners of war. The town was then made a heap of ruins. In 1763 the British government destroyed every vestige of the fortress. Since that time only a few hundred fishermen have lived at Louisburg, and the place remains in the hands of Great Britain.

LOUIS D'OR, a French gold coin which was introduced in 1640, and continued to be coined till 1795. It ranged in value from about $4 to $4.60. The name has been occasionally applied to the French napoleon or 20-franc piece, and to certain German five-thaler pieces.

LOUISIANA, a city and railroad center of Pike county, Mo., on the Mississippi River. It has a college, gasworks, tobacco factories, and the surrounding region produces lumber and fruit. Population, 5,090.

LOUISIANA, State of. The area of the State as recorded in the census of 1890 is 48,720 square miles; the population, 1,118,587; consisting of 554,712 white, 562,893 colored, 315 Chinese, 39 Japanese, and 628 Indians. The bonded indebtedness of Louisiana is $28,133,222, of which $11,759,500 is State, $16,327,222 is municipal, and $46,500 is county indebtedness. In 1884 an act of the legislature provided a commission to revise the laws of the State. The revised statutes have been presented and the work will be continued to include a revision of the civil code, the criminal code and the penal code.

During the past few years many miles of levee have been constructed at a large expense both to the State and to the United States Government. Levee legislation has been most important and has given additional security to territory that before had been continually damaged by overflow.

A recent report on education gives the number of public schools for whites as 1,304; colored, 665; pupils enrolled—white, 67,313; colored, 43,601; with an average attendance of 47,759 white and 31,686 colored pupils; teachers employed—white, 1,696; colored, 670; private schools—white, 256; colored, 16; with 5,888 white pupils and 539 colored.

The total number of youth of school age in the State is 336,137, of whom 117,341 are enrolled in either the public or private schools. The eleventh census shows that while the population of the State has increased 19.01 per cent., the school enrollment has increased 53.52 per cent. The higher education of the State is provided for by the State University, the Agricultural and Mechanical College, the State Normal School, the Lutheran University, and Lulane University.

An immigration bureau has been established, maintained by the State and by private subscription, to secure to Louisiana her proportion of the immigrants to this country. While convict labor, outside of public works, is still permitted, a strong feeling in opposition thereto is manifest.

Recent reports give the following as the yield of the staple crops: cotton, 475,079 bales; sugar, 409,669 barrels molasses, 208,259 hhd. sugar, and 331,358 barrels of sugar; rice, 1,155,256 barrels; maize, 13,459,734 bushels. In addition, a large amount of tobacco is raised, besides various fruits. Many are

engaged in the manufacture of shingles, cotton-seed oil, and tobacco for the market.

After much discussion, the proposed amendment to the constitution, granting an extension of license for twenty-five years to the Louisiana State lottery after 1894, was submitted to the people and defeated.

The largest city in the State is New Orleans; the capital since 1880 is Baton Rouge.

The following is a full list of the governors of the State:

TERRITORY OF ORLEANS.

*The term of office is four years; the present term expires in May, 1896.

LOUISVILLE, the largest city of Kentucky, a port of entry and capital of Jefferson county, is situated on the Ohio, 130 miles below Cincinnati. The river here forms a series of rapids—the "Falls of the Ohio"—descending 22 feet in 2 miles; except at high-water, steamboats pass these by a canal. The city, which covers about 20 square miles, is handsomely built, with wide and regular streets, on a level plain and sloping up from the river. It has a Roman Catholic cathedral and 150 other churches, a law school, four medical colleges, colleges of dentistry and of pharmacy, a school of pharmacy for women, and a good system of public schools. Here also is the state institution for the blind; altogether there are some forty public and private charitable institutions. Louisville is the greatest market for tobacco in the world, and has large pork-packing establishments, distilleries, and tanneries. Extensive manufactures of ploughs, furniture, castings, gas and water-pipes, machinery, flour, and cement are also carried on. The city is the terminus of a number of railway lines; the Ohio is crossed here by two railway bridges, one of them nearly a mile long. Louisville was founded in 1778, and in 1780 named in honor of Louis XVI. of France, whose troops were then assisting the Americans in the war of independence. A great part of the town, including the tobacco-market and the city hall, was destroyed by a cyclone on March 27, 1890. Pop. (1890), 161,129.

LOVEJOY, ELIJAH PARISH (1802–1837), an American Abolitionist. In 1827 he established a school in St. Louis, Mo., and in 1829 became editor of a political paper. In 1833 he was licensed to preach by the Presbyterian Church, and then established a religious paper called the "Observer," in which he condemned slavery. Repeated threats of mob violence compelled him to remove his paper to Alton, Ill., and his press was there destroyed three times by mobs. At the fourth attack, he and his friends defended the office, and compelled the mob to withdraw, but when Lovejoy opened the door he was instantly pierced by five bullets.

LOVEJOY, OWEN (1811–1864), an American Abolitionist, brother of the preceding. In 1838 he became pastor of the Congregational Church at Princeton, Ill., and then held anti-slavery meetings in all parts of the State until 1854, when he was chosen a member of the legislature. In 1856 he was elected to Congress, and remained there until his death.

LOVELL, JOHN, born Nov. 20, 1835, at Farnham, Surrey, England, began his journalistic career in 1856, at the small town of Guildford, in Surrey. Thence he went north, where he became connected with several of the leading provincial journals, and at the same time contributed to the periodical literature of the day. He was appointed editor of "Cassell's Magazine," in succession to Mr. Moy Thomas, in 1868, but relinquished that post in 1869 to take the management of the Press Association. Having successfully launched and carried on this undertaking, he, in 1880, retired to take the editorship in chief and general management of the "Liverpool Mercury." In addition to contributing largely to periodical literature, Mr. Lovell edited the *Nouveau Robinson Suisse*. He died in 1890.

LOVELL, MANSFIELD, born in Washington, D. C., Oct. 20, 1822; graduated at West Point in 1842, and served in Texas and Mexico. He resigned to enter the Confederate service, and in October, 1861, was commissioned major-general, and given command of the defenses of New Orleans. He withdrew his troops when the forts were captured; afterward commanded a division at Corinth, and succeeded Gen. L. Polk in 1864. He died in New York, June 1, 1884.

LOW, THE HON. SETH, LL.D., was born at Brooklyn, New York, Jan. 18, 1850. He graduated at Columbia College in 1870, and immediately entered the mercantile house of his father, in which in 1875 he became a partner. In 1881 he was nominated as an independent candidate for the mayoralty of his native city and was elected. He served for two terms (1882–1885), and during his administration accomplished much in purifying municipal politics. On leaving that office he again became engaged in active business until his election in 1889 to the presidency of Columbia College, of which he was already a trustee. The degree of LL.D. was conferred upon him by the University of the State of New York in 1889, and by Harvard University in 1890.

LOWE, MAJOR-GENERAL SIR DRURY CURZON DRURY, K.C.B., was born in 1830, in England. He entered the army in 1854, and became a full colonel in 1871. He served with the 17th Lancers in the Crimea, and also in the Indian mutiny. He commanded his regiment in the Zulu war, and led the charge at the conclusion of the battle of Ulundi. He went out to South Africa again in 1881 to command the cavalry there, but did not arrive in the country in time to see active service. In the Egyptian expedition of 1882 he commanded the cavalry brigade, and for his services he was created K.C.B., and received the thanks of Parliament and also the second class of the Osmanleh.

LOWE, EDWARD CLARKE, D.D., born near Liverpool, England, Dec. 15, 1823; was educated in Liverpool at a private school, and afterward at Oxford, where he entered under Rev. W. Jacobson, afterward bishop of Chester, at Magdalen Hall in 1842, whence he was elected to the Bible clerkship at Lincoln College in June, 1844, where he was a pupil of the late Mark Pattison. He graduated B.A. in 1846, and was ordained deacon in September of the same year, and priest in September following. In January, 1850, he opened, as head master at Hurstpierpoint, a middle school, and remained in that office till the end of 1872, when he was appointed provost of the Midland district of St. Nicholas' College. In September, 1873, he was preferred to a canonry in Ely Cathedral.

LOWE, Edward Joseph, F.R.S., born Nov. 11, 1825. In 1840 he began that valuable series of daily meteorological observations which was continued to April, 1882. Mr. Lowe has written several books on meteorology and botany, and has contributed many papers in science to the various British societies.

LOWE, Sir Hudson, a British general, born at Galway, Ireland, in 1769, died in London, July 10, 1844. Entering the army in 1787, he served in various parts of the Mediterranean, aided in the conquest of the Ionian Islands and became their first governor, and was afterwards for some time attached to the Prussian army under Blücher. In the spring of 1816 he became governor of St. Helena, with the custody of Napoleon, who had, landed there in the previous October. The strictness of Lowe's watch of his charge brought upon him bitter attacks from Napoleon's friends and admirers. He published a defense of his conduct in *Mémorial rélatif à la Captivité de Napoléon a Ste. Hélène* (2 vols., Paris, 1830). In 1825 Sir Hudson Lowe was appointed commander of the forces in Ceylon.

LOWELL, a manufacturing city of Massachusetts, situated on the Merrimac River. The site is uneven and hilly and the river falls 33 feet, affording great hydraulic power, which is controlled by a chartered company. Steam power, however, is now very largely used in the large mills and workshops. These include a large number of cotton and woolen factories. In 1890 there were 103 factories doing a business of $34,505,083. Unusual attention is paid to the well-being of the work-people. Pop. (1890), 77,696. See Britannica, Vol. XV, p. 29.

LOWELL, a post-village of Kent county, Mich., situated at the confluence of the Grand and Flat rivers. It has manufactories of flour, axes, and furniture. Pop. (1890), 1,829.

LOWELL, Francis Cabot (1775–1817), an American merchant, son of John Lowell, the statesman. He was the first to introduce cotton manufacture into the United States, and the factories at Waltham, Mass., were established by him. The city of Lowell was named in his honor.

LOWELL, James Russell, LL.D., D.C.L., born at Cambridge, Mass., Feb. 22, 1819. He graduated at Harvard College in 1838, and studied law, but soon abandoned it for literature. Before leaving college he published a class poem. A volume of miscellaneous poems, entitled *A Year's Life*, appeared in 1841; a new collection containing *A Legend of Brittany*, *Prometheus*, and others, in 1844; *Conversations on Some of the Old Poets*, containing a series of well-studied criticisms, both in prose and verse, giving indications of Mr. Lowell's interest in the various political and philanthropic questions of the day, and of his attachment to those principles of which he has since been the champion, in 1845; a third collection of poems, and *The Vision of Sir Launfal*, founded on a legend of the search for the San Graal, in 1848; *A Fable for Critics*, in which he satirically passes in review the literati of the United States, and his most remarkable work, *The Biglow Papers*, a collection of humorous poems on political subjects, written in the Yankee dialect, in 1848. *Fireside Travels*, including graphic papers on Cambridge in old times, and the second series of the *Biglow Papers* appeared in 1864. In 1869 he published *Under the Willows, and Other Poems*; and near the close of the same year, *The Cathedral*, an epic poem; in 1870, a collected volume of essays, entitled *Among my Books;* and in 1871 *My Study Windows. Three Memorial Poems* appeared in 1876; and in 1881 a new edition of his complete works in five volumes was issued. In 1855 he succeeded Longfellow as professor of modern languages and belles-lettres in Harvard College. The degree of D.C.L. was conferred upon him in 1873 by the English University of Oxford, and that of LL.D. by Cambridge in 1874. From 1857 to 1862 he was editor of the "Atlantic Monthly," and he had previously been connected editorially or otherwise with "The Pioneer," a magazine of high character, the "Anti-Slavery Standard," "Putnam's Monthly," and, from 1863 to 1872, was editor of the "North American Review." He has also been a lecturer before the Lowell Institute, in Boston, on the British poets. Toward the close of 1874 he was offered the post of minister to Russia, which he declined; but in 1877 accepted that of minister to Spain, from which he was transferred in January, 1880, to that of minister to Great Britain. On the change of administration in 1885 he resigned this position and returned to the United States. The speeches which he delivered in England have been republished. Mr. Lowell died Aug. 11, 1891.

LOWELL, John (1743–1802), an American statesman. In 1762 he was admitted to the Massachusetts bar, and in 1778 was a member of the legislature from Boston. In 1782–83 he was a member of the Continental Congress, and in 1784 was one of the commission to decide boundary disputes between New York and Massachusetts. In 1789 he was made United States judge for his State, and in 1801 became chief justice of the first circuit, including Maine, New Hampshire, Massachusetts, and Rhode Island.

LOWELL, John (1769–1840), an American political writer, son of the preceding. He was admitted to the practice of law at the Massachusetts bar, in 1789, but after practicing with marked success till 1803 he devoted himself entirely to literature.

LOWELL, John (1799–1836), an American philanthropist, son of Francis Cabot Lowell. From 1817 to 1831 he was engaged in commerce, and then spent the remainder of his life in travel in the United States, Europe, Asia Minor, Egypt, Arabia, and Hindustan. He bequeathed $250,000 for the maintenance in Boston of courses of free lectures on religion, science, and art, and the Lowell Institute since 1839 has continued its operations with marked success.

LOWELL, Percival, born in Boston, March 13, 1855, and graduated from Harvard University in 1876. He has traveled much in the far East. While in Japan in 1883, he was appointed foreign secretary and counselor to the Corean Special Mission to the United States. He returned to Corea the same year and spent the winter in Söuel, its capital. He is a member of the Royal Asiatic Society, of Japan.

LOWELL, Robert Traill Spence, an American clergyman, grandson of John Lowell, the statesman, and elder brother of James Russell Lowell, the poet, born in 1816. In 1839 he began the study of theology, and in 1842 was ordained a priest in the Church of England. He then became bishop's chaplain in the Bermuda Islands, and later was rector at Bay Roberts, Newfoundland. In 1847, on account of failing health, he returned to the United States, and began a mission among the poorer people of Newark, N. J. From 1859 to 1869 he was rector of Christ Church, Duanesburg, N. Y., and then for four years was head master at St. Mark's school, Southborough, Mass. From 1873 to 1880 he was professor of the Latin language and literature in Union College. Mr. Lowell contributed much to magazines and was the author of several books of merit. His verse and prose show a strong personality, a delicacy of expression, and a forcefulness in conception. He died in 1891.

LOWRY, Robert, an American clergyman, born in 1826. He entered the Baptist ministry in 1856, and then had charges in New York city, and Brooklyn, N. Y., West Chester and Louisburg, Pa., and Plainfield, N. J. From 1880 to 1886 he was president of the Baptist Sunday-School Union of New Jersey.

LOWTHER, The Right Hon. James, M. P., was born near Leeds, England, in 1840, and educated at Trinity College, Cambridge. He was elected member of Parliament for York in the Conservative interest, and continued to sit for that city until 1880. In September of 1882 he was elected member for North Lincolnshire, which constituency he represented until November, 1885. He was under secretary of state for the colonies from February, 1874, till February, 1878, when he was appointed chief-secretary of Ireland, which office he held until the resignation of Lord Beaconsfield's government in May, 1880.

LOWVILLE, a post-village, the county-seat of Lewis county, N. Y., one and a half miles west of the Black River, in a rich agricultural region producing cheese, butter, and lumber. The village contains a noted academy founded in 1808, and also foundries and mills. Pop. (1890), 2,511.

LOYSON, Charles, formerly known under the monastic name of Père Hyacinthe, born at Orleans, France, March 10, 1827. He studied at St. Sulpice, and in 1851 was ordained priest, and taught philosophy and theology at Avignon and Nantes. Subsequently entering the order of Carmelites, he became known as a powerful preacher, attracting crowded and enthusiastic audiences of all ranks of society to the Madeleine and Notre Dame in Paris. Almost as remarkable as his eloquence was the boldness with which he denounced existing abuses in the church; and in 1869 the General of his order imposed silence on him. Hyacinthe replied by a letter in which he called for a thorough reform of the church, and was excommunicated by the Pope. He then preached independently, resuming his family name, Loyson. In 1869 he visited the United States, and on his return married in London an American lady. He was afterwards for a short time curé of a congregation of Liberal Catholics at Geneva, Switzerland, and in 1879 he established an independent congregation in Paris under the name *L'Église Gallicane*. He has published a number of sermons and lectures.

LUBBOCK, Sir John, banker and man of science, was born in London, April 30, 1834. At fourteen he entered his father's banking house, and in 1856 became a partner. He was chosen honorary secretary to the association of London bankers, first president of the institute of bankers, and served on the international coinage commission, as a member of the public school commission, the advancement of science commission, the education commission and the gold and silver commission. In 1870 he was returned for Maidstone, and, on losing his seat in 1880, was returned for London University—since 1886 as a Liberal Unionist. As a politician he has devoted himself chiefly to financial and educational subjects, and has succeeded in passing more than a dozen important public measures, including the bank holidays act, the bills of exchange bill (which regulates the whole law relating to checks, bills, and promissory notes), and the shop hours bill. He was vice-chancellor of the University of London from 1872 to 1880; is a trustee of the British Museum; and has acted as president of many of the scientific societies, being president of the British association in 1881, president of the London chamber of commerce, and chairman of the London county council. He is best known as a man of science, for his researches on the ancient vestiges and remains of man, and on the habits of insects, especially bees and ants; and has written many popular works.

LÜBECK, a free city and state of the German Empire. (See Britannica, Vol. XV, p. 31). The latest official reports give the area at 115 square miles, and the population at 76,485. In religion the Protestant population numbered 74,544 (97.5 per cent.) and the Roman Catholics, 1,143 (1.2 per cent.). The estimated revenue in 1891 amounted to 3,528,007 marks, and the expenditures to about the same amount. Of the revenue about one-sixth is from public domains, chiefly forests; one-fourth from interest and the rest from taxation. One-fourth of the expenditures is for interest on and reduction of the public debt, which in 1891 was 13,265,424 marks. The imports by sea were valued at 59,911,500 marks; the exports at 122,341,000 marks.

LÜBKE, Wilhelm, a German art historian, born at Dortmund, in 1826. After studying at Bonn and Berlin, he soon attracted attention by his articles on the history of art published in the "Deutsche Kunstblatt." In 1855 he was made professor of the history of architecture in the Berlin school of architecture. Lübke made several journeys in Italy, France, and Belgium for the purpose of studying church architecture. In 1861 he became professor of archæology and the history of art in the Polytechnic School at Zürich, and in 1866 he was called to a similar position at Stuttgart.

LUCAN, George Charles Bingham, Third Earl of, a British general, born April 16, 1800; died Nov. 10, 1888. He was educated at Westminster, and on leaving school entered the army. He accompanied the Russian troops under General Diebitsch as a volunteer against the Turks in 1828; succeeded to the title and large estates in Ireland in 1839; and as commander of a division of cavalry in the Crimea fought at the Alma, Balaklava, and Inkermann. Appointed lieutenant-general in 1858 and G.C.B. in 1869, he became field-marshal in 1887.

LUCAS, Seymour, A.R.A., was born in London on Dec. 21, 1849. Leaving school at the age of fifteen, he spent three months in the studio of a sculptor and a further term of nine months with Gerard Robinson, the wood-carver, from whom he received his first notions of composition. His uncle, John Lucas, the painter, then articled him to his son, John Templeton Lucas, who was to teach him the art of painting. During the term of his apprenticeship Mr. Lucas attended the evening classes of the St. Martin's school of art, in connection with South Kensington; and in 1871 he became a student of the Royal Academy, exhibiting his first picture there in 1872. It was not until 1875, however, that Mr. Lucas contributed to the annual exhibition at Burlington House a work of any mark; this was entitled *By Hook or Crook*. The following year he sent two pictures, *Fleeced*, and *For the King and the Cause;* and in 1877 *Intercepted Dispatches. An Ambuscade: Edge Hill*, appeared in 1878. The technical excellence of all this artist's work is of a high order, and is especially noticeable in *The Gordon Riots*, which was exhibited in 1879. In 1877 he was elected full member of the Institute of Painters in Water Colors, and in 1886 was elected A.R.A. His recent works are *The Armada in Sight* (1880); *Charles Before Gloucester* (1881); *The Favorite* (1882); *A Whip for Van Tromp* (1883); *After Culloden* (1884); *From the Field of Sedgmoor* (1885); and *Peter the Great at Deptford* (1886).

LUCCA, Pauline, was born at Vienna, of Jewish parentage, in 1842, and in 1859, having completed her musical studies, she made her first ap-

pearance in opera at Olmutz. From 1861 to 1872 she was court singer at Berlin. She sang with great success in England and in various continental cities, and in 1872 visited the United States. In 1865 she married Count von Rahden, from whom she obtained a divorce shortly afterward, and married Herr von Nallhoten.

LUCY, Henry W., born at Crosby, near Liverpool, Dec. 5, 1845; was apprenticed to a Liverpool merchant; joined the staff of "The Shrewsbury Chronicle" as chief reporter in 1864; in 1869 went to Paris to attend lectures at the Sorbonne; in January, 1870, returned to London to join the staff of the morning edition of "The Pall Mall Gazette," and in Oct., 1873, joined "The Daily News" as special correspondent, chief of the gallery staff and writer of the parliamentary summary. Mr. Lucy is author of *A Handbook of Parliamentary Procedure* and *Men and Manners in Parliament*. He is a frequent contributor to London and American periodical literature. In 1882 his first novel, *Gideon Fleyce*, was published. In January, 1886, Mr. Lucy accepted the editorship of the "Daily News."

LUDINGTON, a city, the county-seat of Mason county, Mich., on Lake Michigan, at the point where Père Marquette Lake and River enter the larger lake. It is the western terminus of the Flint and Père Marquette Railroad, and is connected with Milwaukee, Wis., eighty-four miles southwest, by a steamer line. It has a good harbor, manufactures shingles and carriages, and contains a foundry and machine-shop. Pop. 7,517.

LUDLOW, a post-village in Windsor county, Vt., situated on Black River and on the Rutland division of the Vermont Central Railroad, twenty-five miles east of Rutland. It has an academy, a foundry, and manufactories of woolen goods, carriages, toys, and machinery. Pop. 1,081.

LUDLOW, FitzHugh, author, born in New York city, Sept. 11, 1836; died in Geneva, Switzerland, Sept. 12, 1870. He was graduated at Union in 1856, after which he began literary life. At college he wrote some popular student-songs, and thereafter contributed to "Putnam's Monthly." From 1858 to 1860 he read law, while editing "Vanity Fair," a comic weekly on the style of the London "Punch." Later he wrote for several New York newspapers on travels, the drama, and fine arts. In 1863 he journeyed overland to California and Oregon, and after a variety of literary occupations went to Europe in June, 1870, to seek relief from slowly wasting consumption. Many of his verses were floated by the newspapers, and he made a hobby of writing on the hasheesh and opium habits. His published volumes are *The Opium Habit* (New York, 1868); *Little Brother* (Boston, 1867); and *The Heart of the Continent* (New York, 1870).

LUDWIG, Karl Friedrich Wilhelm, a German physiologist, born at Witzenhausen, Hessen, in 1816. After studying medicine at Marburg and Erlangen, he was appointed professor of comparative anatomy at Marburg in 1846. From 1849 to 1855 he held the chair of physiology at Zürich. In 1855 he was called to Vienna, and in 1865 he became professor at Leipzig. His investigations in anatomical physiology place him in the front rank of that department of science. Ludwig's principal work is *Lehrbuch der Physiologie des Menschen* (1852–55); but his *Arbeiten aus der Physiologischen Anstalt zu Leipzig*, and his essays in scientific journals contain valuable contributions to physiology.

LUGARD, General, The Right Hon. Sir Edward, G.C.B., born at Chelsea, England, in 1810, was educated at the military college, Sandhurst, and, having entered the army in 1828, proceeded to India, where he served with distinction for many years. During the Afghan war of 1842, he was brigade-major of the 4th brigade; and during the Sikh war of 1845–46, assistant adjutant-general of the first division. Throughout the Punjaub campaigns of 1848–49, he was adjutant-general to the queen's forces. He was made K.C.B. for his services as chief of the staff in the Persian expedition of 1856–57, and was appointed adjutant-general in India at the close of 1857. At the capture of Lucknow, and the subsequent operations against the rebels, he commanded, as brigadier-general, the second division of infantry, and was promoted to the rank of major-general in 1858. He was sworn of the privy council Nov. 3, 1871. He attained the rank of general in November, 1872, and died in 1888.

LUITPOLD, Prince Charles Joseph William, regent of Bavaria, was born at Würzburg, March 12, 1821. He is general and inspector-general of the Bavarian army, chief of the regiment of Bavarian artillery, and proprietor of the 1st regiment of Austrian artillery. He married April 15, 1844, the Princess Augusta, archduchess of Austria. On the death of Louis II., King of Bavaria, in June, 1886, he was appointed regent on account of the mental derangement of Prince Otto, the succeeding titular king.

LUMSDEN, Major-General Sir Peter Slark, G.C.B., C.S.I., was born at Aberdeen, Scotland, in 1829. He entered the Indian army in 1847, and has risen to his present rank by constant and active service, principally on the northwest frontier of India. In 1857 he was employed in a difficult mission to Afghanistan, at the crisis of the Indian mutiny, and discharged his arduous and perilous duties with infinite credit. He accompanied the expedition to China in 1860, and was present in all the actions there, including the assault and capture of the Takee forts. He was adjutant-general to the commander in chief, Sir F. P. Haines, during the last Afghan war, and was appointed commissioner for the demarcation of the northwestern boundary of Afghanistan, July 16, 1884. After the Penjdeh "incident," Sir Peter Lumsden returned home to report on the state of things to the British government, and his place was taken by Colonel (now Sir West) Ridgway. Sir Peter Lumsden is a member of the Council of India, and was made a G.C.B., July 3, 1885.

LUNAWARA, a small state of India, of the Rewacaunta agency, in the province of Gujarat, having an area of 388 square miles, and a population of 75,450. The region is hilly and well wooded. The capital, from which the state derives its name, is 60 miles from Baroda, near the Mahi or Mhye River. Population, 9,059.

LUNDY, a granitic island of Devonshire, in the mouth of the Bristol Channel, 30 miles from St. Gowan's head in Wales. It measures three and a half miles by one, has rocky and precipitous shores, with only one landing place on the south side; and attains an altitude of 525 feet. Here near the southern end of the island, is a lighthouse, built in 1820. The antiquities include prehistoric kists, remains of round towers and a chapel, and the ruined castle of the Mariscoes, from whose time on into the 17th century Lundy was a stronghold successively for pirates, buccaneers, privateers and smugglers. Population in 1881, 177.

LUNDY, Benjamin (1789–1839), an American philanthropist. In 1815 he organized an anti-slavery association at St. Clairsville, Ohio, and in 1822 began the publication of the Mt. Pleasant "Genius of Universal Emancipation," a monthly. Afterwards he removed his paper to Baltimore, then to Washington, and finally to Philadelphia. Lundy was

the first to establish anti-slavery periodicals and to deliver anti-slavery lectures, and probably the first to induce the formation of anti-slavery societies.

LUNEL, a town in the south of France, 14 miles northeast of Montpellier, with a trade in Muscatel wine and brandy. Interesting human remains have been found in a cave at Pondres, six miles north of Lunel. Population, 6,460.

LUNT, George (1803–1885), an American author. In 1827 he began the practice of law in Newburyport, Mass., and soon afterwards became a member of the legislature. Under Gen. Zachary Taylor's administration he was United States district attorney, and just prior to the civil war edited the Boston "Courier." Much of his time was given up to literary pursuits. He wrote several volumes of poems and of prose essays.

LUNT, William Parsons (1805–1857), an American clergyman. From 1828 to 1833 he was pastor of the Second Unitarian Church of New York, and from 1835 to his death was associate pastor of the Unitarian Church in Quincy, Mass.

LUSSAN, Raveneau de, French buccaneer, born in Paris in 1663; died in France about 1710. He was of good family, and at the age of fourteen entered on a military career. In 1679 he went to San Domingo in quest of adventure, and joined the buccaneers under Cornelius Laurent. In the following year he formed a band of his own to act against the Spaniards, and pillaged the town of Redlejo, in Guatemala. In 1686 his band set fire to Grenada. Later, in unison with English pirates, he took part in the capture of Guayaquil. Thereafter his band of about 300 men captured Tehuantepec. At Nueva Legoria his men, having made a journey overland, were surrounded and hemmed in by the Spaniards, but, favored by fog, they found their way to the rear of the entrenched Spaniards, and put them to flight. After much suffering and frequent hazards, Lussan reached France, and published his *Journal du voyage fait à la mer du Sud avec les flibustiers de l'Amerique* (Paris, 1688). It was dedicated to the minister of the navy, and by him and the nation at large was well received.

LUSTRUM, the solemn offering made for expiation and purification by one of the censors in the name of the Roman people at the conclusion of the census. As the ceremony was performed at the end of every five years, the word *lustrum* came to mean a period of five years.

LUTHARDT, Christoph Ernst, a German theologian, born in Bavaria in 1823. After studying theology at Munich he spent some years in teaching. In 1854 he became extraordinary professor of theology at Marburg, and in 1856 he was made professor of theology and New Testament exegesis in the University of Leipzig. Prof. Luthardt has written several works on theological topics, and by these and his periodical publications has exerted a great influence.

LUTTERWORTH, a small town of Leicestershire, on the Swift, 8 miles from Rugby. The fine old church, restored by Scott in 1867–69, contains the pulpit and other relics of Wyclif, who was rector from 1374 till his death on Dec. 28, 1384. He was buried here, but in 1428 his remains were dug up and burned, and the ashes cast into the Swift. "This brook conveyed his ashes into Avon, Avon into Severn, Severn into the narrow seas, they into the main ocean; and thus the ashes of Wickliffe are the emblem of his doctrine, which now is dispersed all the world over." Pop. of parish, 1965.

LUTTRINGHAUSEN, a town of Rhenish Prussia, five miles southeast of Elberfeld. It has manufactories of cloth, calico and silk, hardware and brandy. Population in 1885, 10,216.

LÜTZEN, a small town of 3,501 inhabitants, in the Prussian province of Saxony, famous for two great battles fought in its vicinity. The first, a brilliant victory of the Swedes in the Thirty Years' War, took place on Nov. 6, 1632. The battle on May 2, 1813, was fought somewhat farther to the south, at the village of Grosgörschen. It was the first great conflict of the united Russian and Prussian army with the army of Napoleon in that decisive campaign; and the French were left in possession of the field.

LÜTZOW, Ludwig Adolf Wilhelm, Freiherr von, born in Brandenburg on May 18, 1782, died at Berlin on Dec. 6, 1834, gave his name to a celebrated corps of volunteers, raised in Silesia during the war of liberation in 1813. It included several celebrated men, as Jahn, Theodor Körner, etc., and was renowned for its ardent patriotism and magnificent courage. The men uniformed themselves, and are often spoken and sung of as the "Black Rifles" (*Jäger*). Lützow's wife was the Countess of Ahlefeldt, the friend of Immermann.

LUVERNE, the county-seat of Rock county, Minnesota, situated on Rock River, and on a branch of the Sioux City and St. Paul Railroad. Pop., 1,466.

LUZZATTO, Samuel David, an eminent Jewish scholar, born at Trieste, in Istria, Aug. 22, 1800, died at Padua in 1865. When only 15 years old he published a volume of Hebrew verses. In 1829 he was appointed professor of Biblical literature in the rabbinical college of Padua. Among the Hebrews in Italy Luzzatto was celebrated for deep learning and wise judgment. He wrote against the Cabalists, published some volumes of Hebrew verse and several treatises and commentaries on Jewish theology. He was preparing a version of the Old Testament in Italian when he died. His son, Philoxene Luzzatto (1829–54), was distinguished as a linguist.

LYALL, Edna, the pen-name of Miss Ada Ellen Bayly. She was born and educated at Brighton, England, and commenced her literary career at an early age. Her books have attained a widespread popularity.

LYDIAN MODE, an ancient Greek mode in music, now used only occasionally in modulation from other modes.

LYKENS, a post-village of Dauphin county, Pa., 25 miles from Harrisburg. It is a coal shipping point, and has foundries and lumber mills. Pop., 2,450.

LYMAN, Theodore, an American naturalist, born in 1833. In 1863 he entered the Union army as aid-de-camp to General G. G. Meade, with the rank of lieutenant-colonel, and was present at many of the most important battles of the war. From 1865 to 1882 he was fish commissioner of Massachusetts, and since 1860 has been assistant at the museum of comparative zoölogy in Cambridge. He is a member of many scientific societies, and has written extensively on zoölogy and natural history.

LYME REGIS, a seaport and watering place of Dorsetshire, at the mouth of the Lyme rivulet, five miles southeast of Axminster. The Cobb breakwater, dating from the 14th century, was reconstructed in 1825–26. Miss Mary Anning, the discoverer of the Ichthyosaurus and Plesiosaurus in the Lias rocks here, which are largely quarried, was a native of this place. Population in 1881, 2,048.

LYNCH, Patrick Nilson (1817–82), an American Roman Catholic bishop. In 1840 he became assistant pastor at the cathedral of Charleston, S. C., and from 1844 to 1855 was pastor of St. Mary's

church of that city. In 1858 he was consecrated bishop. His articles on the *Vatican Council*, and *The Blood of St. Januarius* were published in book form.

LYNCH, THOMAS (1749–1779), a signer of the Declaration of Independence. On the organization of the first regiment of South Carolina provincials in 1775 he was commissioned a captain, and in 1776 was elected to a seat in the Continental Congress. On account of failing health he embarked in 1779 for the south of France, but the ship in which he sailed was seen for the last time when a few days out at sea.

LYNCH, THOMAS, born in Wisconsin, Nov. 21, 1844; was a member of the Wisconsin Legislature in 1873 and 1883; graduated from the law department of the Wisconsin University in 1875; was district attorney of the county from 1878 to 1882; in 1883 he moved to Antigo, in Langlade county, where he now resides; was mayor of Antigo in 1885 and again in 1888; was elected to the fifty-second Congress as a Democrat, and was reëlected to the fifty-third Congress.

LYNCHBURG, a city of Virginia, in Campbell county, on the James River. Population in 1870, 6,825; in 1890, 19,709. See Britannica, Vol. XV, p. 105.

LYNE, THE REV. JOSEPH LEYCESTER, called "Father Ignatius," was born Nov. 23, 1837, in London. He was ordained, in 1860, to the curacy of St. Peter's, Plymouth; but left to begin the attempt of restoring monasticism in the Church of England, in 1862. He is the author of many published sermons, poems and hymns: the *Tales of Llanthony; Brother Placidus; Leonard Morris;* and *Tales of the Monastery*. He and his monks claim to follow the ancient rule of St. Benedict, and use the Benedictine breviary for choir office and the Sarum missal of the ante-Reformation Church of England. They wear the old English Benedictine dress. Mr. Lyne's monastic name is "Ignatius of Jesus."

LYNN, a city of Essex county, Mass., located on the north side of Massachusetts Bay, near the foot of the Nahant Peninsula, about ten miles northeast of Boston, with which city it is connected by several railways. Lynn is noted for the manufacture of boots and shoes, mostly women's and children's shoes, which are sent all over the United States. The Thomson-Houston electric factory is located here. It employs some fifteen hundred men and turns out machinery for many electric lighting and power plants. A recent report gives Lynn 152 manufactories with an output of $29,936,711. Population, 55,727. See Britannica, Vol. XV, p. 109.

LYON, MARY (1797–1849), an American educator. From 1814 to 1837 the most of her time was devoted to teaching in various schools, and in the latter year she founded Mount Holyoke Seminary at South Hadley, Mass. From that date to her death she served as its principal. She published *Tendencies of the Principles Embraced and the System Adopted in the Mount Holyoke Seminary* (1840), and *Missionary Offering* (1843).

LYON, NATHANIEL, born in Ashford, Conn., July 14, 1818; died near Wilson's Creek. He was graduated at the United States Military Academy in 1841, assigned as lieutenant of infantry, and served in Florida toward the close of the Seminole war. In the Mexican war he was present at the siege of Vera Cruz, and brevetted captain; at the assault on the Mexican capital he was wounded. At the close of that war he was ordered to California, where in 1851 he was promoted captain. Returning to the East in 1853, he sympathized with the Free State party. He was on duty in Kansas in 1859, and with Gen. William S. Harney in December, 1860, when the governor sent a brigade of militia to coöperate with the national troops in arresting James Montgomery, the Free State leader. In February he was ordered to St. Louis, Mo. There he began to drill and organize the home-guards, and had charge of the arsenal, where his ability and vigilance did much for the Union cause. The home-guards were nearly all German recruits, as the native population and the Irishmen were mostly secessionists. On June 10, 1861, at the head of a body of these German troops, he took possession of Camp Jackson, a secessionist rendezous. A week later he was promoted to brigadier-general of volunteers, and soon afterward was placed in command of the department. He next dispersed the Confederate force at Potosi, and on June 17th defeated a body of Governor Jackson's State militia. On Aug. 2, he defeated General McCulloch at Dry Springs, and eight days later attacked a formidable force under Generals McCulloch and Price at Wilson's Creek, when he was defeated. Here, in the ardor of action, he was twice wounded; nevertheless, keeping his saddle, he led his men to renewed attacks, until his horse was killed and himself shot in the breast by a minie rifle-ball. His death was deeply lamented throughout the Union.

LYONNAIS, a former province of France, bounded on the west by Auvergne and on the south by Languedoc. Its territory coincides nearly with the present department of the Rhone, Loire, Haute-Loire, and Puy-de-Dôme.

LYONS, a city and railroad center of Clinton county, Ia., situated on the Mississippi River. It has extensive nurseries, several excellent schools, and manufactories of wrapping-paper, flour, oil-cans, and carriages. Pop., 5,799.

LYONS, a city, the county-seat of Rice county, Kan., situated twenty-one miles east of Ellinwood. Pop., 1,754.

LYONS, a post-village, the county-seat of Wayne county, N. Y., midway between Syracuse and Rochester, on the New York Central Railroad. It is a peppermint-oil market, and manufactures fanning-mills, and farm implements. A musical academy is located here. Pop., 4,475.

LYONS, RICHARD BICKERTON PEMELL (1817–1887), a British diplomatist. From 1857 to 1865 he was minister to the United States, from 1865 to 1867 ambassador to Turkey, and from 1867 to 1887 ambassador to France. In 1865 he became a member of the privy council, in 1881 was made a viscount, and in 1887 an earl.

LYTTON, EDWARD ROBERT, EARL OF, an English poet, born 1831. After being educated at Harrow and Bonn, he entered the diplomatic service. In 1863 he was secretary of legation at Copenhagen and the next year he served in the same capacity at Athens. He subsequently became chargés d'affairs at Lisbon, at Madrid, and at Vienna; and in 1872 he was appointed secretary of the embassy to Paris. In 1873 he succeeded his father as second Lord Lytton; in 1874 became minister at Lisbon, and in 1876 viceroy of India. The chief events of his viceroyalty were the proclamation of the Queen as Empress of India and the outbreak, in 1879, of the tedious and unpopular Afghan war. In 1880, on the fall of the Beaconsfield government, he resigned, and in 1887 he was sent by Lord Salisbury as ambassador to Paris. Lord Lytton published (chiefly under the nom de plume, "Owen Meredith") several volumes in prose and verse. He died at Paris Nov. 24, 1891.

# M

## MABERY—MACOMB

MABERY, Charles Frederic, born in Maine, Jan. 13, 1850; graduated at Lawrence Scientific School at Harvard in 1876, and was assistant in chemistry there from 1875 to 1883. In the last-named year he was called to the chair of chemistry in the Case School of Applied Science, at Cleveland. Professor Mabery has made many experiments with regard to the production of platinum by electricity. He is a member of several scientific societies.

MACADAM, John Loudoun, born in Ayr, Scotland, Sept. 21, 1756; died Nov. 26, 1836. He became noted by the introduction of the system of road-making known as "macadamizing," which he introduced into Scotland and afterward into England.

MACALISTER, Alexander, F.R.S., was born in Dublin, 1844, and educated at Trinity College, Dublin. In 1869 he was appointed professor of zoölogy in Dublin University, and of anatomy in 1872. In 1883 he accepted the professorship of anatomy at Cambridge, and he was elected fellow of St. John's College. He is F.R.S. and member of the senate of the Royal University of Ireland, and has published *Introduction to Animal Morphology* and *Morphology of Vertebrate Animals*.

MACALISTER, James, born in Glasgow, Scotland, April 26, 1840; came to this country when a boy and graduated at Albany Law School. He became superintendent of public schools in Milwaukee, Wis., in 1873; was afterward regent of Wisconsin normal schools, and superintendent of public schools in Philadelphia. He has published various text-books and manuals of instruction.

MACAPA, a town of Brazil, in the province of Para, on the left bank of the Amazon, three miles north of the equator. It has a good harbor, and considerable trade in timber and ornamental woods. Population about 7,500.

MACAULAY, James, was born in Edinburgh, May 22, 1817. His early education was received at the Edinburgh Academy. In 1830 he entered the University of Edinburgh, where he took degrees in art and in medicine, attending also the classes in theology. After graduating in 1841, Dr. Macaulay studied in Paris, and traveled in Italy and Spain. In 1851 he became joint editor of the "Literary Gazette," and retained the appointment till 1857. In the following year he became editor of the "Leisure Hour" and the "Sunday at Home."

MACCALUBA, a remarkable mud volcano, 138 feet in height, situated six miles north of Girgenti, in Sicily. The sides are studded with numerous small cones, which usually emit hydrogen and occasionally mud and stones, often sending them to a great height.

MacCONNELLSVILLE, a post-village, and the county-seat of Morgan county, Ohio, situated on the Muskingum River. It contains a woolen factory, a foundry, and a tobacco factory. There are extensive salt works in the vicinity. Pop., 1,771.

MACE, a heavy club about 5 feet long, surmounted by a metal head, frequently spiked, which was used as a weapon by knights and warlike churchmen in the Middle Ages. The ornamental maces, borne as an ensign of authority, may be traced to the 12th and 13th centuries, when princes armed their guards with spikeless maces against the sudden attacks of the assassins. The need passed away, but the maces remained as symbols of rank. In the Congress of the United States the sergeant-at-arms has a silver mace.

MACHIAS, the county-seat of Washington county, Me., on Machias River, at the head of navigation. It is a port of entry, and contains a custom-house, foundry, sash and blind factory, and many good schools. Lumbering and ship-building are important industries. Pop., 2,035.

MACKAY, Charles, a Scotch poet, born at Perth, in 1814, died in 1889. The publication of a small volume of poems in 1834 led to his becoming assistant editor of the "Morning Chronicle." From 1844–47 he was editor of the "Glasgow Argus;" he acted on the literary staff of the "Illustrated London News," and filled the post of New York correspondent of the "London Times," during the civil war. The "London Review," a weekly journal which he established in 1860, was not a success. Down to the time of his death, Dec. 24, 1889, he issued many volumes of poetry and prose, and was a contributor to "Blackwood's Magazine," the "Nineteenth Century," and other periodicals. Two of Mackay's songs, *There's a Good Time Coming*, and *Cheer, Boys, Cheer*, had an extraordinary vogue; four hundred thousand of the first having been sold, without putting anything into his pocket. *Gossamer and Snowdrift*, his posthumous poem, was published in 1890.

MACKENZIE RIVER, in North America, has its origin as the Athabasca in the Rocky Mountain Lake, in British Columbia, flows over 600 miles to Lake Athabasca, and 240 as the Slave River to Great Slave Lake, conveying the waters of the Great Slave Lake to the Arctic Ocean at Mackenzie Bay, after a final course which is reckoned at 1,045 miles, making a total river system of nearly 2,000 miles. It drains an area of little less than 600,000 square miles. The Mackenzie received its name from Sir Alexander Mackenzie (1755–1820), by whom it was discovered and first navigated in 1789.

MACKEY, Albert G., an American writer on Freemasonry, born at Charleston, S. C., in 1807. In 1838 he became demonstrator of anatomy in the Medical College of South Carolina. In 1844 he gave himself up to the pursuit of literature. His principal work is an *Encyclopædia of Freemasonry*.

MACKINAW, or Mackinac, an island three miles long by two broad, in the Strait of Mackinaw, which connects Lakes Huron and Michigan; on the island is the village of Mackinaw, and on an eminence 200 feet above it is Fort Mackinaw.

MacLEANSBOROUGH, a village, the county-seat of Hamilton county, Ill., situated in the center of the county, and fifty miles southeast of Centralia. It is the trade center of a prosperous agricultural district. Pop. 1,355.

MacMINNVILLE, a post-village, the county-seat of Warren county, Tenn. It contains woolen and cotton mills, an iron foundry, and the MacMinnville Female Academy. Pop., 1,677.

MACOMB, a city, the county-seat of McDonough county, Ill., 200 miles southwest of Chicago. It contains a foundry, excellent schools, and is the seat of McDonough Normal College. Pop., 4,052.

MACOMB, Alexander (1782–1841), an American soldier. He entered the army in 1799, became captain in 1805, and major in 1808. In 1813 he was made colonel of the 3d regiment of artillery, and in 1814 brigadier-general. In 1828 he became major-general and general-in-chief of the army. He died in 1841.

MACOMB, William Henry (1813–1872), a United States naval officer, son of Alexander. In 1834 he entered the navy as midshipman, was made lieutenant in 1847, commander in 1862, captain in 1866 and commodore in 1870. He commanded in numerous important naval actions, always exhibiting great courage and good judgment.

MACON, a city in Georgia, beautifully located in the middle of the State. Nine railroads meet here and give excellent connections in all directions. Macon has extensive manufactories of iron, machinery, cotton-goods, cotton-seed oil, etc., and a large wholesale and retail trade. Population in 1890, 22,746. See Britannica, Vol. XV, p. 166.

MACON, the county-seat of Noxubee county, Miss., 198 miles north of Mobile. The Mobile and Ohio Railroad shops are located here. Pop., 1,565.

MACON, or Macon City, a railroad center and the county-seat of Macon county, Mo., 170 miles northwest of St. Louis. It has manufactories of farming-implements, wagons, etc. Pop., 3,371.

MACON, Nathaniel (1757–1837), an American statesman. He served as a private throughout the Revolution, although several offices were urged on him, and then became a member of the North Carolina senate. From 1791 to 1815 he was a United States Congressman, and then, till 1828, a United States Senator.

MacPHERSON, the county-seat of MacPherson county, Kan., thirty-six miles south of Salina. It has flour-mills and the chief industries of the region are sheep-raising and agriculture. Pop., 3,172.

MacCARTHY, Denis Florence, an Irish poet and translator, born in Dublin in 1817, died April 7, 1882. He first became known through his contributions to the "Nation." His collected *Ballads, Poems and Lyrics*, founded upon the patriotic traditions of the Irish, appeared in 1850, and in 1853 he published six of Calderon's dramas translated into the meters of the original. Further installments of the latter followed in 1861, 1867, 1870, and 1873. In 1872 appeared *Shelley's Early Life*, and in 1879 he wrote the ode for the Moore centenary. In recognition of literary merit he received a pension in 1871, and in 1881 a medal from the Royal Academy of Spain.

MacCUNN, Hamish, a Scotch composer, born in Greenock, March 22, 1868. After study under local teachers, in 1883, he won a scholarship at the Royal College of Music. His progress there was so rapid that in the following year he was able to resign it. In 1888 he was appointed a junior professor of harmony at the Royal Academy. He is regarded as one of the most promising composers of the day. He is a pronounced upholder of nationality in music, and his works are distinctly Scottish in character and subject.

MacDONALD, Sir John Alexander, an eminent Canadian statesman, was born in Glasgow, Scotland, Jan. 11, 1815 (died in 1891), and with his parents emigrated five years later to Canada. He was educated at Kingston, called to the bar in 1836, and appointed a Q. C. in 1846. He represented Kingston in the Canada assembly from 1844 till the union of the provinces in 1867, and in the Dominion Parliament till 1878, when he was defeated; but he afterwards sat for Victoria, British Columbia, and for Carleton and Lennox, and was again returned by his old constituency in 1887. Before the union he had been receiver-general in 1847, commissioner of crown-lands in 1847–48, attorney-general for Upper Canada in 1854–58, succeeding Sir Allen Macnab as leader of the conservatives, and premier in 1856, and again attorney-general in 1858–62 and 1864–67. In 1867, when the new constitution came into force, he was called upon to form the first government for the new dominion, and was minister of justice and attorney-general of Canada until he and his cabinet resigned in 1873. He was again returned to power in 1878, and was successful in the elections of 1882 and 1887. In 1878 his success was owing to the adoption of a policy of protection for native industries, which discriminates against the productions of all other countries, not even excepting Great Britain. Sir John was mainly instrumental in bringing about the confederation of the British North American provinces, and in securing the construction of the Inter-Colonial and Pacific Railways. He was chairman of the London colonial conference, 1866–67, when the act of union was passed by the Imperial Parliament; and in 1871 was appointed one of the British commissioners for the settlement of the Alabama claims. He was made a privy-councilor in 1872, K.C.B. in 1867, and G.C.B. in 1884. He received the degree of D.C.L. from Oxford in 1865, and afterwards doctorates from three Canadian colleges.

McDONOGH, John, born Dec. 29, 1779; died Oct. 26, 1850. When he died he left the bulk of his fortune, about $2,000,000, to the cities of Baltimore and New Orleans for the establishment of free-schools. The McDonogh labor-schools were established, at which seventy boys are annually received to learn farming and elementary English branches.

MacDONOGH, Thomas (1783–1825), a United States naval officer. He entered the navy as midshipman in 1800, was promoted lieutenant in 1807, and master-commander in 1813. In August, 1814, he gained a victory over the British fleet for which he received a gold medal from Congress, and numerous civic honors from cities and towns. The Mediterranean squadron was his last command. He died on his homeward voyage.

MacFARREN, Sir George Alexander, an English composer, born in London, March 2, 1813, died Oct. 31, 1887. He studied at the Royal Academy of Music, where he became professor of harmony in 1838. In 1875 he was appointed principal of the academy, and also professor of music at Cambridge University. He was knighted in 1883. MacFarren's earliest dramatic work, *The Devil's Opera*, was produced in 1838, and he afterward brought out a long series of operas, cantatas, oratorios, overtures, and sonatas, besides some hundreds of songs, many of which were popular. He stands higher, however, as a writer on the theory of music than as a composer.

MacGREGOR, a city of Clayton county, Ia., on the Mississippi River. It has good schools and manufactories of wagons, carriages, and windmills. Pop., 1,160.

MacGREGOR, John, an English canoeist and philanthropist, born at Gravesend, Jan. 24, 1825, and educated at Dublin, and at Trinity College, Cambridge, where he graduated as a wrangler. In 1847 he entered the Inner Temple and was called to the bar in 1851. He made a tour of Europe, Egypt, and Palestine (1849–50); and a subsequent visit to the United States and Canada bore fruit in *Our Brothers and Cousins* (1859). He published an account of a canoe journey in 1865, under the title of *A Thousand Miles in the Rob Roy Canoe*. Other narratives of canoe voyages on the Baltic, Zuyder Zee, and Jordan followed, all of which have been very popular. He died July 16, 1892.

MacHALE, John, an Irish archbishop and author, born at Tubbernavine, County Mayo, in 1791, died in 1881. After being educated at the Roman Catholic College of Maynooth, he was made professor of theology there in 1814, and was raised to the episcopate in 1825. In 1834 he became archbishop of Tuam. He strove zealously to rehabilitate the Irish language as a literary vehicle.

MacKENZIE, Alexander Slidell (1803–1848), a United States naval officer. He entered the navy in 1815 as midshipman, was made lieutenant in 1825, and commander in 1841. He was on active duty in the Mediterranean, the West Indies, the Brazilian waters, and the Pacific, and in 1846 was sent on a private mission to Cuba. In the Mexican war he was at the siege of Vera Cruz and the storming of Tabasco.

MACKENZIE, Alexander, M.P., ex-premier of the Canadian Dominion, was born in Perthshire, Scotland, Jan. 28, 1822. He was educated at Perth and at Dunkeld, after which he emigrated to Canada. For some years he edited the Lambton "Shield," a reform journal. He entered Parliament in 1862 as member for Lambton, and represented that constituency in the Canadian assembly until confederation. In 1867 he was returned to the Dominion Parliament, and concurrently represented West Middlesex in the Ontario legislature during the years 1871–72, holding the office first of provincial secretary, and afterward of provincial treasurer. In October of the latter year he resigned his seat in the local house; and in 1873, on the defeat of the Macdonald ministry, was called upon to form an administration in the Dominion Parliament, and accepted the office of premier and minister of public works. This post he held until the fall of his government in 1878. In 1875 he visited the mother country, when he was presented with the freedom of the Scottish towns of Irvine, Dundee, and Perth. In 1881, on the occasion of a second visit to his native land, he was presented with the freedom of Inverness. He died April 17, 1892.

MACKENZIE, Alexander Campbell, was born in Edinburgh in 1847, and sent to Germany at the age of ten, to study music. Four years later he entered the dual orchestra, at Schwarzburg-Sondershausen, and remained in Germany till 1862, when he went to London to study the violin under M. Sainton. The same year he was elected king's scholar at the Royal Academy of Music. In 1865 he returned to Edinburgh as a teacher of the pianoforte. The composition which made him famous was his opera *Colomba*, based upon Mérimée's celebrated story. He was elected principal of the Royal Academy of Music in February, 1888, succeeding the late Sir George MacFarren.

MACKENZIE, Sir Morell, M.D. (London), was born at Leytonstone, Essex, England, in 1837, and educated at the London Hospital Medical College, Paris and Vienna. He founded the hospital for diseases of the throat, Golden Square, 1863; and in the same year obtained the Jacksonian prize from the Royal College of Surgeons for his essay on diseases of the larynx. He was soon afterward elected assistant-physician to the London hospital, becoming in due course full physician, and was appointed lecturer on diseases of the throat, which position he held until his death. He was a corresponding member of the Imperial Royal Society of Physicians of Vienna, and of the Medical Society of Prague, and an honorary fellow of the American Laryngological Association. Doctor Mackenzie was the author of numerous publications on laryngological subjects, and in particular of a systematic treatise in two volumes, on *Diseases of the Throat and Nose*, which is acknowledged to be a standard work. Sir Morell Mackenzie received his title from Queen Victoria for his services to the late Emperor Frederick of Germany. He died Feb. 3, 1892.

McALEER, William, an American statesman, born in County Tyrone, Ireland, June 6, 1838. He came to Philadelphia with his parents in 1851; was educated in the public and private schools; was president of the commercial exchange, and a director of the chamber of commerce of Philadelphia. In politics a Democrat, he served two years in the common council. In 1873 he was elected a member of the board of guardians of the poor of Philadelphia for a term of three years, and was reëlected for five consecutive terms; was elected a State senator in 1876, serving four years. In 1890 he was elected to Congress from the 3d Congressional district of Pennsylvania. He was reëlected to the 53d Congress.

McALL MISSION, the largest Protestant mission in France. It was started in 1871 by the Rev. R. W. McAll and his wife, and is there known as "Mission Populaire Evangélique de France." It possesses over 100 stations (some forty-odd in Paris alone), and is indorsed by the clergymen of all Protestant churches.

McALLISTER, Matthew Hall, born in Georgia, Nov. 26, 1800; died in California in December, 1865. In 1850 he removed to California, where he became United States circuit judge, in 1855.

McALPINE, William Jarvis, born in New York city in 1812; became a civil engineer and had charge of the Erie Canal improvements, the building of a dry-dock in the United States navy yard at Brooklyn, and the construction of the original Chicago and Albany, N. Y., water-works. He died Feb., 1890.

McCABE, Charles C., an American clergyman, popularly known as "Chaplain McCabe," born at Athens, Ohio, Oct. 11, 1836. He became a traveling Methodist minister in 1860; chaplain of infantry in 1862; was taken prisoner at the battle of Winchester in 1863, and upon his release made the tour of the Union in the interest of the Christian Commission. Since the war he has traveled in the interest of the Board of Church Extension, and in 1884 he was elected missionary secretary of the Methodist Episcopal church.

McCALL, George Archibald (1802–1868), an American soldier. From 1831 to 1836 he served as aide to Gen. E. P. Gaines, and then in the Florida and Mexican wars, receiving the brevets of major and lieutenant-colonel. From 1850 to 1853 he was inspector-general of the army. In 1861 he was made brigadier-general, and after two years of active service resigned on account of poor health. He wrote *Letters from the Frontier* (1868).

McCARTHY, Justin, an Irish journalist, author and statesman, born in Cork, Nov. 22, 1830. He became attached to the staff of the "Northern Times," Liverpool, in 1853, and in 1860 entered the reporter's gallery of the House of Commons for the "Morning Star," becoming its foreign editor the following autumn, and chief editor three years later. He resigned his post in 1868 and devoted the next three years to an unusually complete tour of the United States. Soon after his return he became connected with the "Daily News," but he has also contributed, among other magazines, to the "London," the "Westminster," and the "Fortnightly Review." He entered the House of Commons in 1879 as member for Longford, and has identified himself throughout with the Home Rule party. In 1890 he was chosen as leader of the Irish Parliamentary party in place of Mr. Parnell. McCarthy's novels have, perhaps, extended his name farther than his political triumphs. His other works are *Con*

*Amore;* a collection of essays, *Critical Notice of George Sand; Prohibitory Legislation in The United States; Modern Leaders,* and *A History of our Own Times,* an exceedingly readable work, clear and useful, though neither erudite nor exhaustive. In 1889 he published his popular *History of the Four Georges.*

McCHEYNE, Robert Murray, an eminent Scotch divine, who has been called "the George Whitefield of Scotland," born at Edinburgh, May 21, 1813, died at Dundee, March 25, 1843. He wrote hymns and published sermons, both of considerable merit.

McCLELLAN, George Brinton, was born at Philadelphia, Dec. 3, 1826. He graduated at West Point in 1846. His services until 1857 were mainly scientific. In 1857 he resigned to accept the presidency of the Illinois Central Railway. At the beginning of the Civil war it fell to McClellan to cross into West Virginia and begin the campaign, which ended with the surrender of the Confederate forces at Rich Mountain and the expulsion of the opposing armies from his department on July 14, 1861. He was called to Washington, given command of the army, and, when Scott retired, was made commander of all the armies, until March, 1862, when his command was reduced again to the army of the Potomac. His campaign on the Peninsula is historical. On September 2d he was recalled and given command of "all the troops for the defense of the capital." He found the armies in almost complete confusion; he organized and united them; attacked Lee's rear so vigorously at South Mountain as to force him to turn and fight, and defeated him after a two days' battle; and all this work was done in fifteen days, September 2–17. He was removed, however, Nov. 7, 1862, for slowness in pursuing Lee, and Burnside became his successor. McClellan was nominated for the Presidency in 1864. Defeated by Lincoln, he retired to private business as a civil engineer, in which he was very successful. He was elected governor of New Jersey in 1877, serving in 1878–81. He died at Orange Mountain, N. J., Oct. 29, 1888.

McCLERNAND, John Alexander, an American lawyer, born in 1812. In 1832 he began the practice of law in Shawneetown, Ill., and in 1835 established the "Shawneetown Democrat." From 1836 to 1842 he was a member of the State legislature, and from 1843 to 1851 served in Congress. In 1859 he was again chosen to Congress, and served till the beginning of the civil war, when he resigned and was appointed brigadier-general of volunteers in the Union army. He was present at many important battles, and gained the rank of major-general. In 1864 he resigned from the army.

McCLINTOCK, Sir Francis Leopold, a British explorer, born in 1819. At the age of 12 he entered the navy, and in 1845 was promoted to a lieutenancy. He was a member of an Arctic expedition sent in search of Sir John Franklin in 1848, and of another sent out in 1849. In 1851 he was promoted to the rank of commander, and put in charge of the *Intrepid,* one of the five vessels sent to the polar regions under Sir Edward Belcher. In 1857 Lady Franklin gave him the command of the expedition sent out by her, which resulted in solving the mystery of Sir John Franklin's fate. In 1860 he was knighted; in 1871 was made rear admiral; in 1877 vice admiral, and in 1884 full admiral. He is the author of *The Voyage of the "Fox" in the Arctic Seas* (1860).

McCLINTOCK, John, born in Philadelphia, Oct. 27, 1814, graduated at the University of Pennsylvania in 1835, and was ordained in the Methodist-Episcopal Church. For twelve years he held successively the chairs of mathematics and of Greek and Latin in Dickinson College, and from 1848 to 1856 he edited the "Methodist Quarterly Review." He was afterward pastor of St. Paul's M. E. Church, New York, and in 1867 became the first president of Drew Theological Seminary at Madison, N. J. He was D.D. of the University of Pennsylvania, and LL.D. of Rutgers, and was the author of numerous text-books and essays. He died March 4, 1870.

McCLOSKEY, John (1810–1885), an American Roman Catholic cardinal. In 1834 he was ordained priest, and in 1837 was appointed pastor of St. Joseph's Church, New York City. In 1841 he became the first president of Fordham College, New York, but held the post only a year. In 1844 he was consecrated bishop, and made coadjutor of the diocese of New York. In 1864 he was made archbishop, and in 1875 was created cardinal, being the first of that rank in the American church.

McCLURE, Alexander K., born in Perry county, Penn., Jan. 9, 1828; edited newspapers in his native State, and served in the legislature as a Republican. He supported Lincoln in 1860 and 1864, and Greeley in 1872; was an unsuccessful candidate for mayor of Philadelphia, and in 1874 established the "Times" of that city, of which he is still editor.

McCOOK, Alexander McDowell, an American soldier, born in 1831. He entered the army in 1852, and served against the Apaches till 1857. From 1858 to 1861 he was instructor of infantry tactics at West Point, and then became a colonel of the 1st Ohio regiment. He commanded in the first battle of Bull Run, in the Tennessee and Mississippi campaign, and in the campaigns of Perryville, Stone River, Tullahoma, and Chickamauga, and was engaged in the defense of Washington. In 1880 he was appointed colonel of the 6th infantry, and later became commandant of the School of Instruction for Infantry and Cavalry at Fort Leavenworth, Kan. He now commands the department of Arizona.

McCOOK, Daniel (1834–1864), an American soldier. He was admitted to the Ohio bar in 1860, and then removed to Leavenworth, Kan. At the beginning of the civil war he became a captain in a local company of volunteers, and served at Wilson's Creek. He then served as chief of staff of the 1st division of the army of the Ohio in the Shiloh campaign, and in 1862 became colonel of the 52d Ohio infantry. In 1864 he was selected to lead the assault that was made on Kenesaw Mountain, and took his brigade directly up to the Confederate works. On reaching the top of the enemy's works he was fatally wounded and died a few days later.

McCOOK, Edwin Stanton (1837–1873), an American soldier. When the civil war began he raised a company for the 31st Illinois regiment, and served at Fort Henry, Fort Donelson, in the Vicksburg, Chattanooga, Atlanta, and other campaigns, and in the march to the sea under Sherman. Gen. McCook was three times severely wounded, and received the brevet of major-general of volunteers. He was shot and killed in Yankton, Dak., while presiding over a public meeting.

McCOOK, Henry Christopher, an American clergyman, born in Ohio, July 3, 1837. He served as first lieutenant and chaplain in the army, and then held pastorates at Clinton, Ill., and St. Louis, Mo. In 1869 he was made pastor of the 7th Presbyterian Church of Philadelphia. Doctor McCook, who is D.D. of Lafayette University, is vice-president of the American Entomological Society, and has written on natural history and other subjects.

McCOOK, Robert Latimer (1827–1862), an American soldier. He acquired a large law practice in Cincinnati, Ohio. In 1861 he organized the 9th Ohio regiment, and was made its colonel. He served with distinction in several battles, and was promoted brigadier-general of volunteers. He was shot while lying in an ambulance on the battlefield near Selma, Ala.

McCOOK, Roderick Sheldon (1839–1886), a United States naval officer. He entered the navy in 1859, became lieutenant in 1861, lieutenant-commander in 1865, and commander in 1873. During the civil war he served with distinction in several important engagements. On account of failing health he retired from active service in 1885.

McCORMAC, Sir William, was born at Belfast, Ireland, Jan. 17, 1836. He was educated in the Belfast Institution, in Dublin and in Paris. He saw service at Metz and Sèdan, during the Franco-German war, as surgeon-in-chief of the Anglo-American ambulance. He is one of the senior surgeons, and lecturer on surgery, at St. Thomas' Hospital, and consulting surgeon to the French Hospital. He is a fellow of the English and Irish Colleges of Surgeons, and examiner in surgery in the University of London. In 1881 he acted as honorary secretary-general of the International Medical Congress. Sir W. McCormac is the author of *Work under the Red Cross*, and treatises on *Antiseptic Surgery*, and *Surgical Operations*, besides numerous surgical papers contributed to medical journals and addressed to medical societies.

McCORMICK, Cyrus H., the inventor of the reaping machine, born at Walnut Grove, Va., Feb. 15, 1809, died in 1884. He went to Cincinnati in 1845, and to Chicago in 1847. His reaper, patented in 1834, won him wealth and distinction. He was a liberal promoter of education, and founder of the Theological Seminary of the Northwest.

McCOSH, James, an American educator, born in Scotland in 1811. In 1835 he was ordained minister of the Church of Scotland, and held pastorates in various places till 1862 when he became professor of logic and metaphysics in Queen's College, Belfast, Ireland. Here he remained till 1868, when he removed to the United States, having been elected president of Princeton College. He resigned the presidency of the college in 1888, but retained the chair of philosophy. Besides numerous contributions to British and American reviews, he has published many philosophical works and essays, and some occasional sermons and addresses.

McCRARY, George W., was born in Evansville, Ind., Aug. 29, 1835. With his parents in 1836 he went to that part of Wisconsin Territory which afterward became the State of Iowa. In 1857 he was a member of the State legislature, and from 1861 to 1865 he was State senator from Keokuk, and chairman of the committee on military affairs. In 1868 he was elected to Congress, and served until March, 1877. In 1876 Judge McCrary introduced in Congress the electoral commission bill, which resulted in the choice of Rutherford B. Hayes as President. When President Hayes formed his cabinet McCrary was given the war portfolio, which he held two years. He resigned to accept the judgeship of the United States circuit court, to which he was appointed in December, 1879. In March, 1884, he resigned his judgeship to become general consulting attorney for the Atchison, Topeka, and Santa Fé Railroad Company. He died in St. Joseph, Mo., June 23, 1890.

McCULLOCH, Ben (1811–1862), an American soldier. He supported the Texan revolutionists in their struggle for independence, and in 1839 was elected to the congress of Texas. In 1845 he became a member of the first legislature, and was made major-general of the state militia. At the beginning of the Mexican war he raised a company of Texas rangers, and later showed great courage as a spy. In 1852 he was appointed United States marshal, and in 1857 was appointed a commissioner to adjust the difficulties with the Mormons of Utah. In 1861 he was made a brigadier-general in the Confederate army, and did good service in several engagements. He was killed by the bullet of a sharpshooter while reconnoitering.

McCULLOCH, Hugh, a Secretary of the United States Treasury, born in 1808. He studied law in Boston, and then went to Fort Wayne, Ind., where, in 1835, he became cashier of a branch of the State bank. From 1856 to 1863 he was president of the bank of the State of Indiana, and then became Comptroller of the Currency. In 1865 he was appointed Secretary of the Treasury, and held office till 1869. From 1871 to 1878 he was engaged in banking in London, and in 1884 was again appointed to the office of Secretary of the Treasury, holding the post till the end of Arthur's administration.

McDONALD, Edward F., an American statesman, born in Ireland, Sept. 21, 1844. In politics he is a Democrat. In 1874 he was elected a member of the New Jersey assembly, and in 1877 and 1879 was a member of the board of chosen freeholders of Hudson county, N. J. In 1889 he was elected a State senator, and in 1890 was elected a representative from the seventh congressional district of New Jersey to the Fifty-second Congress. He served in the Union army during the war of the rebellion. He died Nov. 5, 1892.

McDONALD, George, a British poet and novelist, born at Huntley, Aberdeenshire, in 1824. He studied theology with the intention of becoming a Congregational minister, but decided afterwards to devote himself entirely to literature. His views are extremely broad and liberal, and his style of writing has a peculiar charm. As a depicter of a peculiar and interesting phase of Scottish life, Dr. McDonald has achieved much popularity and success.

McDONALD, Joseph Ewing, born in Ohio, Aug. 29, 1819. At eighteen he entered Wabash College at Crawfordsville, Ind., supporting himself by his own labor; was at Asbury University, 1840–42, and studied law. He was elected attorney-general of the State in 1856. In 1859 he removed to Indianapolis, where he continued to practice law until his death. He served in Congress as a Democrat, in 1849–51; was candidate for governor against Oliver P. Morton in 1864. As chairman of the State Democratic committee in 1872, he reorganized the party and secured the election of a Democratic legislature. He served in the United States Senate from 1875–81 and died June 21, 1891.

McDOWELL, Irvin (1818–1885), an American soldier. In 1838 he became a second lieutenant in the 1st artillery of the United States army, and served till 1841 on the northern frontier. From 1841 to 1845 he was instructor of infantry tactics at the United States Military Academy, and then became aide-de-camp to General John E. Wool. In 1848 he was appointed adjutant-general in the war department in Washington, and in 1856 attained the rank of major. In 1861 he was made brigadier-general, and commanded the Department of Northeastern Virginia and the defenses of Washington, and also the Army of the Potomac at the battle of Bull Run. In 1864 he was given the command of the Department of the Pacific; in 1866 of California; in 1868 of the East, and in 1872 of the South. In 1882 he retired from active service as major-general.

McDUFFIE, George (1788–1851), a governor of South Carolina. He was admitted to the bar in 1814, and in 1818 was sent to the South Carolina legislature. In 1821 he was chosen to Congress as a Democrat, and served until 1834. He was then elected governor of his State, which office he held till 1836, when he retired to private life. From 1842 to 1846, he was a United States Senator. He published, besides numerous addresses, an *Eulogy on Robert Y. Hayne* (1840).

McGEE, Thomas D'Arcy (1825–1868), a Canadian statesman. For a time he was editor of the Boston, Mass., "Pilot," and then went to Ireland, where he was on the staff of the Dublin "Freeman's Journal," and later of "The Nation." In 1848 he established in New York "The American Celt," and then "The Nation." Subsequently he settled in Canada, and established a paper called "The New Era." In 1857 he was chosen to the Canadian parliament, and from 1864 to 1867 was president of the executive council. On the evening of April 7, 1868, when returning from a night session of parliament, he was assassinated at the door of his hotel. He published a volume of poems and several historical works of considerable merit.

McGILL, James, philanthropist, was born in Glasgow, Oct. 6, 1744, and died in Montreal, Canada, Dec. 19, 1813. He emigrated to Canada before the American Revolution, engaged for some time in the Northwest fur trade, and, subsequently settling in Montreal, became a successful merchant there. He was for many years a member of the Lower Canada Assembly, and subsequently a member of the legislative and executive councils. He was noted for philanthropy. He bequeathed to the college in Montreal that bears his name property valued at £30,000 and £10,000 in money; but, in consequence of the increased value of land, these figures convey a very inadequate idea of the present value of his gift to McGill College.

McGLYNN, Edward, an American clergyman, born in 1837. In 1860 he was ordained to the Roman Catholic priesthood, and in 1866 became pastor of St. Stephen's church in New York city. In 1886, on account of his ignoring the Papal demands to appear at the Vatican on a charge of his support of Henry George's land theories, he was excommunicated. In 1887 Doctor McGlynn became president of the Anti-Poverty Society, and in behalf of his economic opinions, he has lectured in nearly all of the principal cities of the United States. In the latter part of 1892 he was reinstated in his clerical functions.

McGUFFEY, William Holmes, an American educator, born in Washington county, Pa., in 1800, died at Charlottesville, Va., May 5, 1873. He became professor in Miami University in 1836; president of Ohio University in 1839, and professor of moral philosophy in the University of Virginia in 1845.

McILVAINE, Charles Pettit (1799–1873), an American Protestant Episcopal bishop. In 1820 he was made deacon, and in 1821 priest. He became pastor of Christ Church, Georgetown, D. C., and later was appointed professor of ethics in the United States Military Academy. In 1827 he was called to St. Ann's church, Brooklyn, N. Y., and in 1831 was made professor of sacred antiquities in the University of the City of New York. In 1832 he was elected bishop, and chosen president of Kenyon College. He was the author of several books and addresses on religious topics.

McINTOSH, James Simmons (1787–1847), an American soldier. In 1812 he entered the United States army as lieutenant, and served throughout the Creek war. In 1817 he became a captain, in 1836 major, and in 1839 lieutenant-colonel. He participated in several important battles of the Mexican war, and was mortally wounded in the assault on Molino del Rey.

McINTOSH, John, an American general, born in McIntosh county, Ga., in 1755, died there in 1826. He served in the Revolutionary war as a lieutenant-colonel of the Georgia militia, defending the fort at Sunbury, in Liberty county, when it was besieged by a strong British force. At the battle of Briar Creek, March 3, 1779, he displayed great bravery, surrendering only when further resistance was impossible. During the last months of the war of 1812–14, he served under Jackson as major-general of the Georgia militia.

McINTOSH, Lachlan (1725-1806), an American soldier. At seventeen years of age he entered a counting-house in Charleston, S. C., and subsequently became a land surveyor at Inverness (now Darien), Ga. In 1776 he was appointed brigadier-general of militia, and two years later accepted a command in the central army under Washington, doing good service throughout the war. In 1784 he was a member of Congress.

McINTOSH, Maria Jane (1803–1878), an American authoress. Her first work was *Blind Alice*, published in 1841 under the pen-name of "Aunt Kitty," and from that time she devoted her life to literature.

MACK, Karl Freiherr von, Austrian general, born in Franconia, on Aug. 24, 1752, entered the military service of Austria in 1770, was in 1797 created field-marshal. After the peace of Campo Formio, he took the field against the French, and occupied Rome; but was unable to retain his hold of the city. In 1805 the emperor put him at the head of 80,000 men, and sent him to check the French advance along the line of the Iller. But the enemy outmanœuvred him, and shut him up in Ulm, and on Oct. 17th, Mack capitulated with his army. Tried by court-martial and condemned to death, his sentence was commuted to expulsion from the army and twenty years imprisonment. In 1808 Mack was liberated, and in 1819 fully pardoned. He died Oct. 22, 1822.

McKEAN, Thomas (1734–1817), a signer of the Declaration of Independence. In 1765 was elected to the stamp-act Congress; became Speaker of the House of Representatives in 1772, and from 1774 to 1783 was member of the Continental Congress. From 1799 to 1808, he was governor of Pennsylvania.

McKEESPORT, a borough of Allegheny county, Pa., on the Monongahela River, fifteen miles southeast of Pittsburgh. It has flour, saw and rolling mills, large manufactories of iron-pipes, glass works foundries, machine-shops, and a distillery. Natural gas is used for fuel to some extent. Population in 1880, 8,912; in 1890, 20,741.

McKENDREE, William, an American Methodist bishop, born in Virginia, July 6, 1757, died in 1835. Originally a Revolutionary officer, he became a preacher in 1788, presiding elder in 1796, and bishop in 1808. He was largely instrumental in planting Methodism west of the Alleghenies and in founding McKendree College at Lebanon, Ill., to which institution he bequeathed 480 acres of land. After 1816 he was senior bishop for 19 years.

McKINLEY, William, an American statesman, born at Niles, Ohio, Feb. 26, 1844. He enlisted in the United States army in May, 1861, as a private soldier in the 23d Ohio Volunteer Infantry, and was mustered out as captain of the same regiment and brevet-major in September, 1865; was prosecuting attorney of Stark county, Ohio, 1869–71; was elected to Congress in 1877; lost his seat by vote of the House in 1884; was reëlected and sat continuously as a member of Congress from 1885 to March 4,

1891. He is author of the protective tariff bill passed by Congress in 1890. In 1891 he was elected governor of Ohio.

McKINNEY, the county-seat of Collin county, Texas. It has large flour mills and is situated in a grain and stock-raising locality. Pop., 2,489.

McKINNEY, Luther F., an American statesman and divine, born in Licking county, Ohio, April 25, 1841. He received a common school education; served as a sergeant in the Union army in 1861–1863; removed to Iowa in 1865, and spent two years in farming and teaching. In September, 1867, he entered the Saint Lawrence University, New York, graduating in 1870; removed to Maine and entered the ministry; removed to New Hampshire in 1873. In politics he is a Democrat, and was elected a Representative from the 1st Congressional district of New Hampshire to the 50th Congress. In 1890 he was elected from the same district to the 52d Congress.

McLANE, Louis (1786–1857), an American statesman. From 1817 to 1827 he was a Democrat in Congress, and then till 1829 served as a United States Senator. From 1829 to 1831 he was minister to England, and then became secretary of the Treasury. In 1834 he retired from political life. In 1845–46 he again served as minister to England.

McLANE, Robert Milligan, an American diplomatist, born in 1815. In 1837 he joined the army and took an active part in the Seminole war as a lieutenant. In 1839 he was on a military survey of the northern lakes, and in 1841 went to Europe to examine the system of dykes and drainage in Holland and Italy. In 1843 he began the practice of law at the Delaware bar, and in 1845, 1847 and 1849 was elected to Congress. From 1854 to 1856 he was United States commissioner to China, and in 1859 was appointed minister to Mexico. In 1877 he was elected to the Maryland Senate, and in 1888 to the National Congress, receiving a reëlection in 1880. In 1883 he became governor of Maryland, and in 1885 was appointed minister to France.

McLAREN, William Edward, born in Geneva, N. Y., Dec. 13, 1831, graduated at Washington and Jefferson College, Pennsylvania, in 1851, and afterward at the Alleghany Presbyterian Theological Seminary in 1860. For three years he served as a missionary in South America. On his return to the United States he decided to enter the Protestant Episcopal ministry, in which he was ordained in 1872. In September, 1875, he was elected bishop of Illinois. When, two years later, two dioceses were set apart from his own, he retained that part of the State now included in the diocese of Chicago, over which he still presides.

McLAWS, Lafayette, an American soldier, born in 1821. He entered the United States army in 1842 and was in active service till 1861, when he became a colonel in the Confederate army. A little later he was commissioned a brigadier-general, and in 1862 was promoted major-general. He participated in nearly all the important battles of the civil war, and at the close went into business at Savannah, Ga.

McLEAN, John (1785–1861), an American jurist. In 1807 he began the practice of law at Lebanon, Ohio, and in 1812 was elected to Congress, receiving a reëlection two years later. From 1816 to 1822 he was judge of the State supreme court, and then was appointed commissioner of the general land office. From 1823 to 1829 he was postmaster-general, and in 1830 became associate justice of the United States Supreme Court.

McMAHON, Marie Edme Patrice Maurice de, Duc de Magenta, marshal of France and second president of the French Republic, born at Sully Saône-et-Loire, in 1808. He came from an Irish Catholic family settled in France. He was educated at the Military School of St. Cyr, and took part in the expedition to Algiers. McMahon distinguished himself in the assault on Constantine in 1837. In 1845 he rose to be colonel; in 1848 general of brigade, and in 1852 general of division. During the Crimean war he captured by a spirited assault the Malakoff, which was the key to the defenses of Sebastopol. For this achievement he was made a senator in 1859. At the opening of the Italian war in 1850 he commanded the second corps of the army of the Alps. At the battle of Magenta, on June 4, he arrived just in time to make it a decisive victory. For this service he was created Duke of Magenta and marshal of France.

In 1870 when the Franco-Prussian war broke out McMahon commanded the first army corps which had to defend Alsace. But he was defeated at Wörth and afterwards at Sedan. At the latter place he was chief in command, but was wounded at the beginning of the engagement. In 1871, as chief of the army at Versailles, he wrested Paris from the commune. When Thiers resigned the presidency in 1873, McMahon was chosen to succeed him; but he was too conservative for the majority of the Republicans. When the latter demanded the removal of some Bonapartist generals, McMahon resigned the presidency, Jan. 30, 1879. He has since lived in retirement.

McMASTER, John Bach, born in Brooklyn, N. Y., June 29, 1852; graduated at the College of the City of New York in 1872, in 1877 became instructor in civil engineering at Princeton College, and in 1883 professor of American history in the University of Pennsylvania. He has written a *History of the United States from the Revolution to the Civil War*, a *Life of Benjamin Franklin*, and other works.

McMILLAN, James, United States Senator from Michigan, born in Hamilton, Ontario, May 12, 1838. In 1855 he removed to Detroit, where he entered upon a successful business life. He was elected to the United States Senate in 1888. His term of office expires in 1895.

McMILLIN, Benton, born in Kentucky, Sept. 11, 1845. He was graduated from the University of Kentucky. He removed to Tennessee in 1871 and was a representative in the Tennessee legislature in 1874. He has represented the fourth district of Tennessee in Congress since 1879 and was reëlected to the 53d Congress.

McPHERSON, Edward, LL.D., born in Gettysburg, Penn., July 31, 1830; graduated at Pennsylvania College, and began literary work in Philadelphia. From 1859 to 1863 he served in Congress as a representative, and in the beginning of 1864 became clerk of the House of Representatives, which office he held until 1873. He has since been engaged in journalism in his native State. Mr. McPherson, who is M.A. of Princeton and LL.D. of the University of Pennsylvania, has published several historical works and a hand-book on politics.

McPHERSON, James Birdseye (1828–1864), an American soldier. He entered the army in 1853, became second-lieutenant in 1854, lieutenant in 1858, captain and lieutenant-colonel in 1861, colonel, brigadier-general of volunteers, and major-general of volunteers in 1862, and brigadier-general in the regular army, in 1863. He took part in many important battles of the civil war, always displaying a correct judgment, coolness in danger, quick perception, knowledge of ground, and untiring energy. He was killed near Atlanta, Ga., while in command of the Army of the Tennessee. His statue in bronze stands in one of the public parks in Washington.

McPHERSON, John R., born in New York, May 9, 1832; received a common school and academic education; removed to New Jersey, in 1859; was a member of the State senate of New Jersey in 1871–74; was elected to the United States Senate as a Democrat, to succeed F. T. Frelinghuysen, Republican; took his seat March 5, 1877; was reëlected in 1883 and again in 1889. His term will expire March 3, 1895.

McTYEIRE, Holland Nimmons, an American bishop of the Methodist-Episcopal Church, South, born in 1824. In 1851 he became editor of the New Orleans "Christian Advocate," and in 1858 of the Nashville "Christian Advocate," and in 1866 was elected to the episcopate. In 1873 he became president of the board of Vanderbilt University.

McVEAGH, Wayne, born in Phœnixville, Pa., April 19, 1833; admitted to the bar in 1856; captain of cavalry, 1862; minister to Constantinople, 1872; member of the commission to investigate the affairs of Louisiana in 1877; appointed attorney-general of the United States in 1881; resigned in 1881.

MacWHIRTER, John, A.R.A., was born in 1839, near Edinburgh, Scotland. He was elected an associate of the Royal Scottish Academy in 1863. In the following year he went to London, and was elected an associate of the Royal Academy on Jan. 22, 1879. He was elected an honorary member of the Royal Scottish Academy in 1882; and elected member of the Royal Institute of Painters in Water Colors the same year.

MADAGASCAR. For general article on Madagascar see Britannica, Vol. XV, pp. 168–177. The area of the island is now estimated at 228,500 square miles; total length, 975 miles; breadth at widest point, 358 miles. Population, about 3,500,000.

By a treaty signed at Tamatave, Dec. 12, 1885, a French resident-general, with a small military escort, resides at the capital, and the foreign relations of the country are regulated by France, which occupies a district around the Bay of Diego-Suarez as a colony. By the Anglo-French agreement of Aug. 5, 1890, the protectorate of France over Madagascar was recognized by Great Britain, but this has never been agreed to by the Malagasy government, and will probably not be acknowledged by them. The native government retains absolute independence in all domestic legislation and control of the other tribes of the country.

The principal exports ($825,000 per annum) of Madagascar are cattle, hides, gum-copal, india-rubber, rafia bast, and rice, and, more recently, ebony and other valuable woods; coffee, sugar, and vanilla are also being cultivated by Creole settlers. The chief imports ($810,000 per annum) are cotton goods, ironmongery, crockery, and rum. The principal trade is from the eastern ports to Mauritius and Réunion, and there is also now an increasing trade from the western side of the island with the South African colonies. The soil of the coast plains, especially of the eastern side, is fertile, and could supply large quantities of all tropical productions. Iron is abundant, especially as magnetite, and also as hæmatite and ironstone, and the Malagasy are skillful in the smelting and working of this as well as other metals. Copper apparently exists in great quantity in certain districts, and there also tin is said to be found. Galena is found abundantly near Mount Ankàratra, and from this lead for bullets is obtained, and silver is being extracted from it. Gold of excellent quality has recently been found in many parts of the interior, and is now being worked by foreign capitalists as well as by the native government. Sulphur occurs in beds near some of the extinct volcanoes. There are as yet no roads or wheeled vehicles in Madagascar, so that the country is in some respects very backward, although there is no lack of manual skill among the people, who excel in weaving, in straw-work, and in carpentry, as well as in the working of gold and silver.

Very recently younger and more enlightened governors and other officers have been placed at all the principal ports and chief towns of the interior. Three-fourths of Madagascar is still heathen, but European and native missionaries are every year advancing steadily into the unenlightened regions. Queen Ranavàlona III., born in 1862, succeeded in 1883.

MADISON, a village, the county-seat of Morgan county, Ga., about seventy miles from Atlanta. The cotton trade is the chief business, and granite and iron ore are found here.

MADISON, county-seat of Jefferson county, Indiana, on the Ohio River, 86 miles by rail from Indianapolis. It has flour mills, boiler and engine works, steamboat yards, and manufactories of furniture and leather, besides large pork-packing establishments. Pop. (1890), 8,936. See Britannica, Vol. XV, p. 181.

MADISON, a post-village of Morris county, N. J., twenty-eight miles from New York. It is the home of many New York business men, and is the seat of Drew Theological Seminary. Pop. (1890), 1,761.

MADISON, the capital of Wisconsin, founded in 1836, is situated on an isthmus between Lakes Mendota and Monona, 82 miles west of Milwaukee, at the junction of several railways. It contains the State Capitol, University (founded in 1849, and open to both sexes), an asylum for lunatics, and an orphan asylum.

Especially known as an educational center, Madison is second to Milwaukee as a commercial point. The University has grown rapidly until it ranks with the best and has property to the value of $925,000, and during the year ending Sept. 30, 1892, had an income of $236,568. The Washburn Observatory is a part of the University system. The public schools are excellent. The number of teachers is 54; the enrollment of pupils, 1,800.

In addition to the Historical and the University Libraries, here are the free libraries of the State and the city. Water-works, gas and electric lighting and street railways add much to the natural advantages of the city. Plows and other farm implements, wagons, woolens and flour comprise the manufactures. On the lake beach are fine summer hotels and on Lake Monona meets the Monona Assembly, patterned after Chautauqua.

MADISONVILLE, the county-seat of Hopkins county, Ky. It is situated in a tobacco-growing region, and contains tobacco-stemmeries, a pearl-ash and potash factory, flour and planing mills, a cotton-gin, and wagon and carriage manufactories. Coal-fields are in the vicinity. Pop., 2,212.

MÄDLER, Johann Heinrich, a German astronomer, born at Berlin, in 1794, died at Hanover, in 1874. While a teacher in the normal school at Berlin he constructed a map of the moon, which was published in 1836. After this he became successively director of the observatory at Berlin, and at Dorpat, Russia, where he made important observations on Mars and Jupiter, and on double and variable stars. He published *Populäre Astronomie* (1841); *Allgemeine Selenographie*, and *Geschichte der Himmelskunde* (1873). In his work *Die Centralsonne* he presented the hypothesis of a central sun, around which the whole stellar universe revolves. He named the star Alcyone as the central sun.

MADOC, a post-village in Hastings county, Ontario, twenty-eight miles north of Belleville. It

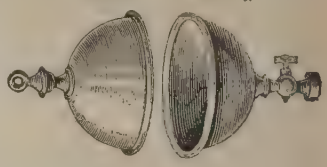
has good water-power, and marble, iron and gold are found in the vicinity.

MAFFITT, JOHN HEWLAND, Confederate naval officer, was born in 1819, and entered the U. S. navy in 1832. At the beginning of the civil war he joined the Confederate service, and in April, 1862, took command of the *Florida*, a Liverpool-built cruiser, in which he emulated the depredations of the *Alabama*. In all, he captured fifty-five merchantmen. He died in 1886.

MAFIA, or MAFFIA a secret Italian organization with a history dating its origin probably in Sicily, and having for its present object the enforcement of private vengeance.* In Southern Italy, and specially in Sicily, its membership was largely made up of murderers and assassins. Its ramifications extended into some cities and towns of the United States, and in New Orleans, where a large Italian population has gathered during several years past, the murderous work of the Mafia in 1888, 1889, and 1890, was constantly on the increase and in June, 1890, culminated in a desperate fight between two factions of the streets of New Orleans. This determined the municipal authorities to break up the organization. In order to prevent this, the Mafia, in October of that year, murdered Hennessey, chief of police. Arrests were made, but owing to the secrecy and influence of the conspirators, the criminals after great delays were brought to trial before a jury which failed to convict. In March, 1891, six of the arrested men had escaped conviction by the jury, and ten were in jail with the prospect also of a similar escape from justice. Multitudes of the people were incensed over the results of the trial, and an indignation mass meeting was called, and after exciting speeches were made, an excited populace, under determined leaders, broke open the jail, and in defiance of all law, shot the Italian prisoners who had been charged with the assassination of Chief Hennessey. This incident led to an exciting controversy between the Italian government and the United States and finally to the withdrawal of the Italian minister.

MAGADOXO, or MUKDISHA, a commercial town on the east coast of Africa, in the Somali country, in Lat. 2° 2′ N. It belongs to the Imaum of Muscat. The town is divided into two parts; one composed wholly of tombs, the other comprising about 150 houses, a mosque, and several minarets of Arabian architecture. The exports are dhurra, beans, peas, cattle, cotton, spices, etc.

MAGDEBURG HEMISPHERES, an instrument invented by Otto von Guericke consisting of two hollow hemispheres, generally made of copper or brass, with their edges accurately fitted together, and one of them furnished with a stopcock. When the edges are rubbed over with grease, pressed tightly together, and the globe thus formed exhausted of air through the cock, the hemispheres, which fell asunder before exhaustion, are now pressed together with immense force.



MAGDEBURG HEMISPHERES.

MAGEE, WILLIAM CONNOR, D.D., archbishop of York, born in Ireland in 1821. He graduated from Trinity College, Dublin, and took holy orders. In 1850 he was appointed joint incumbent, and shortly after sole incumbent of the Octagon Chapel, Bath. In 1860 he succeeded Dean Goulburn as minister of Quebec Chapel, London, and in the following February he was appointed to the rectory of Enniskillen by the University of Dublin. In 1864 he was appointed dean of Cork. In 1868 he was appointed bishop of Peterborough, and in January, 1891, became archbishop of York. He died three months later.

MAGENDIE, FRANÇOIS, a French physiologist, born at Bordeaux, Oct. 15, 1783, died Oct. 7, 1855. He studied at Paris; in 1819 became a member of the Academy of Sciences; and in 1831 professor of anatomy in the Collége de France. He practiced vivisection extensively and by this and other means of observation made important additions to knowledge of nervephysiology, the veins and the physiology of food.

MAGEROÉ, the most northerly of the larger European islands, belonging to Norway and lying close to the coast of Finmark, in the Arctic Ocean It terminates, towards the North Cape, 950 feet in height. Mageroé is 22 miles in length, 15 miles in breadth, and is deeply indented by bays. It supports a few Norwegian and Lappish families.

MAGILUS, a remarkable gasteropod found on the coral reefs of warm eastern seas. The young animal settles on the growing coral at the obvious risk of being gradually surrounded and smothered. This is avoided, however, by an entire change in the form of the shell, which is diverted from its original spiral type and grows out into a long irregular tube. "A neck and neck race is kept up until the mollusk or the coral dies."

MAGINN, WILLIAM, an Irish author, born at Cork, Nov. 11, 1793, died at Walton-on-Thames, Aug. 21, 1842. He was educated at Trinity College, Dublin, where he won a brilliant reputation for precocious scholarship; taught in Cork for ten years; and in 1823 removed to London to pursue a

---

* A letter in an old English magazine tells the following story of the origin of the Mafia organization:

The "Mafia" society is over six hundred years old, having its origin at the revolt of Palermo which took place during an Easter ceremonial in the suburbs of that city in the year 1282. A beautiful young girl and her betrothed, in accordance with the quaint and primitive customs of that people, approached the Church of the Holy Ghost to be united in marriage at its altar; and while the lover sought the venerable padre in the little room at the rear of the building, his bride paused upon its threshold. As she stood, expectant—graceful as a fawn, fair as a dream, her innocent heart throbbing with its new-born happiness—a drunken sergeant of the French garrison, Druet by name, strode up behind her, threw his arm about her waist, and thrust a huge, brutal hand into her pure, snowy bosom. With a cry of horror and fear the poor child tore herself from his polluting grasp and turned to fly, but the heel of her dainty slipper caught in the coping of the stone pavement and she fell, striking her head against a sharp projection of the church cornice.

At that instant the returning lover's eyes fell upon his beautiful mistress—lying lifeless, her white brow gaping with its cruel wound, her long tresses dabbled with her blood. With the savage fury of a wild beast he threw himself upon Druet, bore him to the earth, and drove his stiletto to the wretch's heart crying "Morte alla Francia!" "Death to the French!" There was a moment, a pause of silence, and then that maddened cry became the roar of infuriated thousands. It swelled and deepened; it took more solemn meaning—became nationalized—and then burst forth: "Morte alla Francia Italia anela!" "Death to the French is Italy's cry!" For seventy two hours armed bands, headed by the father and betrothed of the hapless girl, hunted down the hated French, and their search was as the quest of the tiger and bloodhound.

But retribution was to come after this carnival of blood and in dread of the vengeance of the French nation these unhappy people formed themselves into secret organizations with the password and name of the society made up of the initial letters of the words which compose that fateful death cry, thus forming "Mafia." Its object was resistence to oppression, and as the lapse of years added to its power and influence it stretched forth its hands against the rich and mighty in behalf of the poor and the down-trodden. To-day it is but the hideous cloak of the creeping thug and the assassin of the night.

life of letters. His first contributions to "Blackwood's Magazine" appeared in 1819, and from that date, for nine years, scarcely a number appeared without an article from his pen. In 1824 Murray started the short-lived "Representative," a daily newspaper, and Maginn was sent to Paris to act as foreign correspondent. In 1828 he joined the staff of the "Standard," and was one of the originators of "Fraser's Magazine" in 1830. He also contributed numerous papers to the "Quarterly Review," to "Bentley's Miscellany," and to "Punch," and wrote two romances. His writings were characterized by learning and wit. His critical and miscellaneous essays *Homeric Ballads*, and *Shakespeare Papers* were collected in the United States and edited by Dr. R. S. Mackenzie (1855–57).

MAGNUSEN, Finn, a Danish archæologist, born at Skalholt, Iceland, in 1781, died at Copenhagen in 1847. After being educated at Copenhagen he became a lawyer in Iceland in 1803, but was in 1815 appointed as professor of northern antiquities and afterwards as keeper of the archives in Copenhagen. He prepared a dictionary of Scandinavian mythology and a full exposition of its system. But his chief work is a translation of the older *Edda* which he published with abundant commentaries in 1821–23. All his writings indicate excellent judgment and extensive learning.

MAGOFFIN, Beriah, born in Kentucky, April, 1815; died there Feb. 28, 1885. He practiced law, served in the State senate and as probate judge, and in September, 1859, became governor of Kentucky. In this capacity he refused to honor Lincoln's call for troops to suppress the rebellion, and demanded the withdrawal of both Federal and Confederate forces from the State.

MAGRUDER, John B., an American general, born in Virginia about 1810, died in Texas in 1871. He graduated at West Point, and won distinction in the Mexican war; he was wounded at the battle of Chapultepec. He entered the Confederate army in 1861, and served in the Yorktown and Chickahominy campaigns. He was put in command of the Western Department as major-general in 1862, and was distinguished as an able general.

MAHAFFY, John Pentland, an Irish educator, born near Vevay, Switzerland, in 1839. After being educated in Germany, and at Trinity College, Dublin, he was a tutor and lecturer at the latter college, and became a professor of ancient history there in 1869, and Donellian lecturer in theology for 1873–74. He is a thorough scholar and has progressive ideas on education. Professor Mahaffy has written several valuable works on Greek history and literature, and on philosophy.

MAHDI, El, Arabic for "The Well Directed," the title of an Arab, whose proper name is supposed to have been Mahommed Ahmed, who was born near Dongola, Nubia, about 1842; became a monk or dervish, and in 1881 announced himself as the Mahdi or Messiah of the Mahommedan faith. After the overthrow of Arabi Pasha in Egypt, in 1882, the Mahdi raised a very large body of troops in the Soudan, with which he annihilated the Egyptian army under the command of Hicks Pasha. By 1884 he had extended his power to Suakim and the Red Sea, and threatened the frontiers of Egypt. The English, who had for purposes of their own adopted a protectorate over Egypt, found themselves threatened by an insurrection which at any cost had to be suppressed. They sent General Charles Gordon (*q. v.*), unarmed and alone, to Khartoum, who assumed command of the Egyptian troops at that point where the Mahdi speedily blockaded him. The history of the Khartoum expedition, with all its disasters, is told elsewhere, but finally, in January, 1885, Khartoum was captured, and Gordon slain. The British evacuated the entire territory, with the exception of Suakim, and the Mahdi formed a government with its capital at Khartoum. A few months later he died, it is said, of smallpox, and was succeeded by one of his generals, who still (1892) holds the country.

MAHANOY CITY, a borough of Pennsylvania, near the watershed between the Delaware and Susquehanna Rivers. It has about 20 collieries, and an active trade with the other coal mines in the neighborhood. Pop. in 1890, 11,286. See Britannica, Vol. XX, p. 285.

MAHIM, a town of the island of Bombay, 10 miles north of the city of Bombay. The town is ill-built and inhabited chiefly by Christians of Portuguese descent, who have here a church and some other relics of former prosperity. The inhabitants are chiefly employed in fishing, the place being famous for its oysters. Pop., 9,000.

MAHMUD II., Sultan of Turkey, and younger son of Sultan Abdul-Hamid, was born July 20, 1785, and was raised to the throne July 28, 1808. During his reign Greece revolted, the janizaries were destroyed, and Russia defeated the Turks and negotiated the treaty of Bucharest. Although beset on all sides he was the most enlightened sovereign and greatest reformer that had ruled Turkey to that date. He died July 1, 1839, after a reign of thirty-one years.

MAHONE, William, born in Virginia, Dec. 21, 1826; graduated at the Virginia Military Institution in 1847, and engaged in civil engineering. In 1861 he joined the Confederate army, took part in the capture of Norfolk navy yard and engaged in nearly every battle of the Peninsula campaign, on the Rappahannock, and in the campaign around Petersburg. He won the reputation of a fearless fighter, became brigadier and major-general, and commanded a division in A. P. Hill's corps. After the war he returned to engineering and became president of the Norfolk and Tennessee Railroad. He entered politics about 1878, and became the leader of the party which aimed at the "readjustment" (a mild equivalent for repudiation) of the State debt of Virginia. In 1880 he was elected United States Senator, and served from March, 1881, to 1887, but was defeated for reëlection.

MAHONY, Francis, better known by his famous pen-name, "Father Prout," was born at Cork in 1805, and educated for the priesthood at a Jesuit college in Paris, and subsequently in Rome, where he remained for seven years and received ordination. He abandoned the clerical calling about 1834 and joined the staff of "Fraser's Magazine," his contributions to which were republished under the title of, *Reliques of Father Prout*, in 1836. He contributed also to "Bentley's Magazine" from 1837. For some years he acted as Roman correspondent to the "Daily News," and his letters were collected and published in 1847 as *Facts and Figures from Italy, by Don Jeremy Savonarola, Benedictine Monk.* During the last years of his life he lived in Paris, and was correspondent to the "Globe" newspaper, till, in 1864, he retired to a monastery, where he remained till his death, May 19, 1866.

MAILED CHEEKS (*Sclerogenidæ* or *Triglidæ*), a family of acanthopterous fishes, characterized by an extension of certain sub-orbital bones to the gill-covers to form a bony armor for the cheeks. The species are widely distributed in the seas of all parts of the world.

MAIMCHIN, a Chinese trading town on the northern boundary of Mongolia, opposite Kiachta, from which it is separated by a narrow strip of neutral territory. Pop., 3,000.

MAINE, Sir Henry Sumner, an English jurist, born in 1822. After graduating at Pembroke College, Cambridge, he became professor of civil law, there, and was afterwards reader on jurisprudence at the Middle Temple, London, until 1862. In 1870 he was professor of jurisprudence at Oxford University, and since 1877 he was master of Trinity Hall, Cambridge. His most important works are *Ancient Law: Its Connection with the Early History of Society; Village Communities in the East and West*, and *Early History of Institutions* (1875). He died in 1888.

MAINE, State of. For general article on the State of Maine, see Britannica, Vol. XV, pp. 297–302. The census reports of 1890 record the revised figures showing the area and population as follows: Area, 33,040; population, 661,086, a net gain during the last decade of 12,150, or 1.87 per cent Capital, Augusta, with a population of 10,521. The total area here given includes 29,895 square miles of land area and 13,145 of water area.

The population of other cities and towns of the state which had each 8,000 inhabitants or over were as follows:

| Cities. | 1890. | 1880. | Increase. | Per Cent. |
|---|---|---|---|---|
| Auburn | 11,250 | 9,555 | 1,695 | 17.74 |
| Bangor | 19,103 | 16,856 | 2,247 | 13.33 |
| Bath | 8,723 | 7,874 | 849 | 10.78 |
| Belfast | 5,294 | 5,308 | *14 | *0.26 |
| Biddeford | 14,443 | 12,651 | 1,791 | 14.16 |
| Lewiston | 21,701 | 19,081 | 2,618 | 13.72 |
| Portland | 36,425 | 33,810 | 2,615 | 7.73 |
| Rockland | 8,174 | 7,599 | 575 | 7.57 |

* Decrease.

The land areas and populations of the several counties of the State were returned in the census of 1890 as follows—the areas being given in square miles:

| Counties. | Area. | Population. | |
|---|---|---|---|
| | | 1890. | 1880. |
| Androscoggin | 485 | 48,968 | 45,042 |
| Aroostook | 6,700 | 49,589 | 41,700 |
| Cumberland | 1,005 | 90,949 | 86,359 |
| Franklin | 1,660 | 17,053 | 18,180 |
| Hancock | 1,312 | 37,312 | 38,129 |
| Kennebec | 888 | 57,012 | 53,058 |
| Knox | 328 | 31,473 | 32,863 |
| Lincoln | 520 | 21,996 | 24,821 |
| Oxford | 1,892 | 30,586 | 32,627 |
| Penobscot | 3,332 | 72,865 | 70,476 |
| Piscataquis | 3,722 | 16,134 | 14,872 |
| Sagadahoc | 260 | 19,452 | 19,272 |
| Somerset | 3,664 | 32,627 | 32,333 |
| Waldo | 705 | 27,759 | 32,466 |
| Washington | 2,452 | 44,482 | 44,484 |
| York | 920 | 62,829 | 62,257 |

The column of county areas above gives the land areas only.

The following is a full list of the governors of the State of Maine from the beginning, with their dates of service severally:

| | | | |
|---|---|---|---|
| William King | 1820–21 | Anson P. Merrill | 1855–56 |
| W. D. Williamson | 1821–22 | Samuel Wells | 1856–57 |
| Albion K. Parris | 1822–27 | H. Hamlin | 1857 |
| Enoch Lincoln | 1827–29 | Joseph H. Williams | 1857–58 |
| Nathan Cutler | 1829–30 | Lot M. Morrill | 1858–61 |
| Jonathan D. Hunton | 1830–31 | Israel Washburn, Jr. | 1861–63 |
| Samuel E. Smith | 1831–34 | Abner Coburn | 1863–64 |
| Robert P. Dunlap | 1834–38 | Samuel Corry | 1864–67 |
| Edward Kent | 1838–39 | J. L. Chamberlain | 1867–71 |
| John Fairfield | 1839–40 | Sydney Perham | 1871–74 |
| Edward Kent | 1840–41 | Nelson Dingley, Jr. | 1874–76 |
| John Fairfield | 1841–43 | Seldon Connor | 1876–79 |
| Edward Kavanagh | 1843–44 | Alonzo Garcelon | 1879–80 |
| Hugh J. Anderson | 1844–47 | Daniel F. Davis | 1880–81 |
| John W. Dana | 1847–50 | Harris M. Plaisted | 1881–83 |
| John Hubbard | 1850–53 | Frederick Robie | 1883–87 |
| W. G. Crosby | 1853–55 | Joseph R. Bodwell | 1887–89 |
| | | Edwin C. Burleigh, 1889–95. | |

The governor's term of office is for two years; salary, $2,000. Governor Burleigh was reëlected for the term beginning Jan. 1, 1893.

The number of miles of railroad in the State, June 30, 1891, was 1,382, of which 200 miles had been added during the year.

The granite quarries give employment to 4,000 men and the lime and slate quarries to 2,000.

The number of savings banks and institutions for savings at the close of the year, Nov. 31, 1891, was fifty-three, no new ones being organized during the year.

The fifty-three banks represent a total deposit of $50,278,452.44, which amount is divided among 146,668 depositors, making an average of $342.80 to each, showing a total increase in the amount of deposits of $2,497,285.54, and an increase of depositors of 6,147.

The live stock, according to the latest statistics at hand, included 128,000 horses, 300,000 head of neat stock, 351,334 sheep, and 36,931 swine.

The total valuation of the State in 1891 was $260,716,167, and the tax assessed was $4,072,160. The report of the State treasurer, Jan. 1, 1891, showed receipts in the State treasury for 1890 to be $1,495,367.03, and expenditures $1,382,579.27, leaving a balance of $175,466.17 in hand. The total liabilities of the State, Jan. 1, 1891, were $4,250,598, but much of this was due to school and county funds, and the total bonded indebtedness was only $2,602,300. During 1889 the whole debt of the State was refunded and its new three per cent. bonds sold at a premium of three per cent.

The recent important legislation of the State consisted in the adoption of the Australian ballot law, an act defining the scope of the prohibitory law in its relation to the "original package" decision of the United States Supreme Court, and the submission to the people of an amendment providing for an educational limitation to suffrage. A late report of the State commissioner of labor and industrial statistics shows the abandonment of 3,318 farms, whose aggregate value is $1,268,769. See Britannica, Vol. XV, p. 297.

Progress of the State in population by decades: In 1790, 96,540; 1800, 151,719; 1810, 228,705; 1820, 298,269; 1830, 390,455; 1840, 501,793; 1850, 583,169; 1860, 628,279; 1870, 626,915; 1880, 648,936; 1890, 661,086.

MAITLAND, Sir Frederick Lewis, a British naval officer, born in Scotland in 1779. He served with distinction against the French at the siege of St. Jean d'Acre in 1801 and was promoted to a captaincy. In 1815 he was in command of the *Bellerophon*, man-of-war, and was stationed on the coast of France with instructions to prevent the escape of Napoleon, who had arranged to take ship at Rochelle for the United States. Napoleon, finding himself unable to escape, surrendered to Captain Maitland in July, and was by him conveyed in the *Bellerophon* to England. Captain Maitland received a baronetcy and obtained the rank of rear admiral. He died in 1839.

MAKART, Hans, an Austrian painter, born at Salzburg, in 1840, died at Vienna, in 1884. He

studied under Piloty, at Munich. Afterwards he became professor of painting in the Vienna Academy. In 1876 his large picture of *Venice Doing Homage to Catherine Cornaro* was exhibited at the Centennial Exhibition in Philadelphia. It is now in the Berlin National Gallery. All his large canvases are brilliant in coloring, but often too crowded, and some of his themes are sensuous.

MALAN, César Henri Abraham, a Protestant Swiss divine, was born in Geneva, July 8, 1787, and became a pastor of the state church and a regent in the college. Through the influence of American and Scottish friends, he became devoutly evangelical, and many of his works were translated into English. He also wrote several hymns which have become popular.

MÄLAR, Lake, one of the largest lakes, and the most beautiful, in Sweden, measures 80 miles in length from east to west, and has numerous long narrow arms and offsets; area, 650 square miles. It is studded with upwards of 1,200 islands, mostly well wooded. Its east end is close by Stockholm, where its waters are poured into the Baltic Sea. The shores are varied with bays and hills, woods, lawns and cliffs, and are adorned with many castles, country-seats, and villas, including the royal palaces of Drottningholm and Gripesholm.

MALBONE, Edward Greene, painter, born in Newport, R. I., in August, 1777; died in Savannah, Ga., May 7, 1807. He early showed particular interest in the art of design. In 1800 he accompanied Washington Allston to Charleston, S. C. In 1801 both artists visited Europe, but Malbone returned in December of the same year to Charleston, where he permanently located. He made periodical visits to the northern cities, where he painted miniatures of many persons of note. Occasionally he painted landscapes in oil, and figure pieces.

MALCOM, Howard (1799–1879), an American Baptist clergyman. He held pastorates in Hudson, N. Y., and Boston, Mass., and from 1839 to 1849 was president of the college in Georgetown, Ky. From 1851 to 1858 he was president of the University of Lewisburg, Pa., and from 1874 to 1879 of Hahnemann Medical College, Philadelphia. He died in the last-named year.

MALDEGHEM, a town of East Flanders, Belgium, twelve miles by rail east of Bruges. Population, 8,522.

MALDEN, a city of Massachusetts, containing the villages of Linden and Maplewood. Population in 1890, 22,984. In 1890 Malden reported 13 manufactories, with an output of $6,121,271. See Britannica, Vol. XV, p. 327.

MALET, Sir Edward Baldwin, K.C.B., born at the Hague, Oct. 10, 1837. He was educated at Eton, and at Corpus Christi College, Oxford, and entered the diplomatic service in 1854. During the Commune he was *chargé des archives*, was made C.B. July 10, 1871, and promoted to be secretary of legation at Pekin in August of the same year. From 1873 to 1875 he was acting *chargé d'affaires* at Athens, and then proceeded to Rome as secretary of embassy. On April 20, 1878, he was appointed minister plenipotentiary at Constantinople, in the absence of the ambassador. The following year he went to Egypt as agent-consul-general, and a minister plenipotentiary in the diplomatic service; was made K.C.B. in 1881, and received the medal and Khedive's star for his services in Egypt in 1882. In August, 1883, he was promoted to be envoy extraordinary and minister plenipotentiary at Brussels, and ambassador at Berlin, Sept. 20, 1884. Sir Edward Malet was sworn a privy councilor in March, 1885, and in June of the same year was made a G.C.M.G.

MALIBRAN, Maria Felicita (1808–1836), one of the most celebrated mezzo-soprano singers of recent times, born at Paris, March 24, 1808, the daughter of Manuel Garcia, a Spanish singer and teacher of singing. When she was still very young, her reputation extended over Europe. Her father attempted to establish the Italian opera in New York, but without success. She married M. Malibran, a Frenchman, who soon became bankrupt, and she went again upon the stage, and was received with great enthusiasm in France, England, Germany and Italy. Her first marriage having been dissolved, she married M. Beriot, a famous violinist, in 1836; but in September of that year she died at Manchester, whither she had gone to take part in a musical festival. She was a woman of noble heart and high intellect, and her conversation possessed an exquisite fascination.

MALLOCK, William Hurrell, an English author, born in Devonshire, in 1849. He is a nephew of J. A Froude. At Oxford he obtained a prize for an English poem, in 1871. He wrote *Every Man His Own Poet*, and *New Republic* (1876). The last is a dialogue in which representative English persons are brought forward in a very realistic way. It established his reputation as a satirist. Then followed his *New Paul and Virginié* or *Positivism on an Island* (1878). He excited still further sensation by his essay, *Is Life Worth Living*, which is a forcible statement of pessimism, but has since published nothing of special interest.

MALLORY, Stephen Russell (1813–1873), an American statesman. In 1839 he was admitted to the Florida bar and became judge of probate, and in 1845 was appointed collector of customs at Key West. In 1851 he was chosen to the United States Senate, and continued to represent his State until 1861, when he resigned to take part with the Southern States. He was then appointed by Jefferson Davis secretary of the navy, and held the post during the war. From 1866 until his death he practiced law at Pensacola, Fla.

MALMESBURY, James Howard Harris, Third Earl of, born in London, March 25, 1807, died May 7, 1889. He was educated at Eton and at Oriel College, Oxford, graduating in 1827. In 1837 he stood as a Tory for Portsmouth, and in 1841 had just been returned for Wilton, when his father's death called him to the House of Lords. He was foreign secretary under Lord Derby in 1852, and again in 1858–59; and was lord privy seal in 1866–68, and again in 1874–76. In 1884 appeared his *Memoirs of an Ex-Minister*.

MALONE, a post-village, the county-seat of Franklin county, N. Y., on Salmon River, sixty miles from Ogdensburg. It is the center of a large agricultural trade and carries on several manufactures. Pop., 4,986.

MALONE, Edmond, editor of Shakespeare, born in Dublin, Oct. 4, 1741, graduated with credit at the university there. Later he went to London to devote himself to literary pursuits, his first work being a "supplement" to Steeven's edition of Shakespeare. Malone's own edition of the great dramatist was warmly received. His death occurred May 25, 1812.

MALPLAQUET, a village in the French department of Nord. Here, on Sept. 11, 1709, over 90,000 British and Dutch, under Marlborough and Prince Eugene, defeated about the same number of French under Marshal Villars. In this "very murderous battle," as Marlborough called it, the loss of the allies was from twenty to thirty thousand, of the French from six to sixteen thousand.

MALTA. For general article on Malta, see Britannica, Vol. XV, pp. 339–43. The latest figures

place the area at 95 square miles, and that of the neighboring island, Gozo, 20, making a total area (with Comins) of 119 square miles. Population in 1890, 165,662. Chief town and port, Valetta. In 1888 there were a university, a lyceum, and two secondary schools. The governor is appointed by Great Britain; salary, $25,000. Revenue in 1890, $1,306,270; expenditures, $1,334,500.

MAMIANI, Della Rovere, Count Terenzio, an Italian scholar and statesman, born in 1799 at Pesaro, in the Romagna, died at Rome, May 21, 1885. He took a prominent part in the futile outbreak at the accession of Gregory XVI., and was compelled to flee to Paris, whence he returned to Rome in 1848 after the unconditional amnesty of Pius IX., and actually held office for three months in the Papal ministry. He next withdrew to Turin, where he founded his society for promoting Italian unity. On the flight of Pius IX. from Rome to Gaeta he re-entered the political arena and was for a short period foreign minister in the cabinet of Galetti. On the fall of Rome he retired to Genoa; in 1856 he was member of the Sardinian parliament, and in 1860 entered Cavour's ministry as minister of instruction. He was appointed ambassador to Greece in 1861, to Switzerland in 1865.

MANÁOS, capital of Amazonas province, in the United States of Brazil, is on the Rio Negro, 12 miles above its confluence with the Amazon. An ugly whitewashed cathredral rises in the center of the town, which also boasts a custom-house, a tiny fort, and a military hospital. It is a steamboat station, and has a considerable trade in various forest products, but principally in india-rubber. The population, though often stated at 25,000 to 30,000, is under 12,000.

MANASSEH BEN ISRAEL, Jewish scholar, was born at Lisbon in 1604, fled with his father from the Inquisition, and settling at Amsterdam became chief rabbi of the synagogue there. In 1656 he visited England, seeking to secure from Cromwell the readmission of the Jews. He died at Middelburg in 1659. He published texts of various parts of the Old Testament, with notes.

MANBY, George William, inventor of life-saving apparatus for shipwrecked persons, was born in 1765, at Hilgay, England; died Nov. 18, 1854. He served in the militia, and became barrack-master at Yarmouth in 1803. In 1808 he succeeded, with apparatus designed by him, in saving the lives of the crew of the brig *Elizabeth*. A career of usefulness was thus commenced, which he followed for the remaining forty-six years of his life. It was estimated that, by the time of his death, nearly 1,000 persons had been rescued from stranded ships by means of his apparatus.

MANCHESTER, a post-village, one of the county-seats of Bennington county, Vt. It contains Burr and Barton Seminary, a classical school, and is a pleasant summer-resort. Pop., 1,907.

MANCHESTER, a post-town of Chesterfield county, Va., on the south bank of James River, opposite Richmond. It is a manufacturing town. Pop., 9,246.

MANCHESTER, a post-village of Delaware county, Ia., on the west branch of the Maquoketa River, forty-seven miles west of Dubuque. Farming is the chief business, but there is considerable export trade. Pop., 2,344.

MANCHESTER, a post-village and railroad junction of Washtenaw county, Mich., fifty-five miles west of Detroit. It has medicinal springs, a brewery, foundry, saw and planing mills. Pop., 1,191.

MANCHESTER, the largest city of New Hampshire, and one of the greatest manufacturing centers of New England. The Merrimac River falls here 54 feet (Amoskeag Falls), and supplies ample water-power for driving a number of mill and machine works. In the value of its cotton and woolen fabrics Manchester ranks the fourth city in the United States. Population in 1870, 23,536; in 1880, 32,630; in 1890, 44,126. See Britannica, Vol. XV, p. 465.

MANCHESTER, a post-village of Adams county, Ohio, on the north bank of the Ohio River. It is a shipping point for farm produce, and has manufactories of furniture. Pop., 1,965.

MANCÉ, Jeanne, born in France in 1606, died in Montreal, Canada, 1673. Having consecrated herself to the church in early life, she accepted the invitation of Madame Buillon to take the direction of a hospital to be founded by her in Montreal. Finding that a colony, about going to Canada under the auspices of the Society of Montreal, had refused to embark unless a nurse accompanied them, she determined to attend them. Not only was she the nurse but she was the administrator of the colony, who obeyed her as a parent. About nine months after arrival at Quebec, Montreal was founded, in 1642. Mlle. Mancé, the first to decorate an altar in the new city, began at once the erection of the hospital. Three times she returned to France in behalf of the colony, and once she furnished the money to send the governor, while she remained to keep up the courage of the colonists, with only seventeen men able to bear arms. Upon the return of the governor, the war with the Iroquois was concluded, the hospital was completed, and not only Montreal but the whole of Canada was saved to France.

MANCHINEEL (*Hippomane mancinella*), a tropical American tree of the natural order *Euphorbiaceæ*, celebrated for the poisonous properties of the acrid milky juice with which every part of it abounds. A drop of this juice, which is of a pure white color, burns like fire if it falls upon the skin, and the sore which it produces is very difficult to heal. The Indians of tropical America use it for poisoning their arrows. The fruit is not unlike a small apple, and the wood is well suited for cabinet-making.

MANCINI, Pasquale, an Italian statesman, born at Naples in 1820. After graduating in his native city he became professor of jurisprudence there. As a member of the Neapolitan parliament he opposed the king and had in 1848 to flee to Turin, where he became professor of international law. In 1860 he became minister of justice and religion in the new Italian government. He was a leader of the liberal party in the first Italian parliament in 1861, and in the next year he was also minister of education. Mancini resides at Rome where he is professor in the university as well as deputy in parliament. He has published *Diritto Internazionale* (1873). His wife, Laura Beatrice Oliva Mancini (1823–1869), was a noted poetess. Many of her poems had reference to the political condition of Italy.

MANCO CAPAC, first Inca of Peru, died in Peru about 1107. He is supposed to have been a foreigner who gathered the native tribes on the borders of Lake Titicaca, and pretended to have brought them a new revelation in which he set himself forward as the offspring of the sun. He taught the men of the forest to till the earth, and the women to weave and tend their households, abolished human sacrifice, taught of an unknown supreme being, and offered subordinate homage to the sun, moon and stars. After a time Manco Capac laid the foundations of the city of Cuzco, surrounded it with villages, and divided the Peruvians into several tribes. He raised temples adorned

with gold and silver dedicated to the sun. He lived to see his people prosperous, after a quiet reign of thirty or forty years. The Peruvians worshiped the memory of Manco Capac with superstitious reverence.

MANDAN, a thriving town, the county-seat of Morton county, N. Dak., about five miles west of Bismarck. It is the seat of the State Reform School. Pop., 1,328.

MANDANS, a small tribe of North American Indians living at present on a reservation of 8,640,000 acres in the basin of Yellowstone and Powder Rivers in western South Dakota and eastern Montana. An annual appropriation of $75,000 is made for this tribe, together with two other tribes that occupy the same reservation. The Mandans were found in 1805, by Lewis and Clarke, 1,600 miles up the Missouri, living in two villages. In 1822 a census of the tribe made its population 1,200, and in 1832, when living at Fort Clarke, their number was estimated at 2,000. The Sioux were always their most bitter enemies and caused them severe losses in the early day. These invasions and the small-pox had reduced their number in 1837 to 145. They, however, always maintained their tribal government and gradually increased in number and strength. Though friendly to the white man and possessing village government, no missionary work has ever been done among them. Their schools are but weak attempts. They raise corn and potatoes and breed horses, but there are no cattle or proper implements. The Mandans are of light complexion and gray hair, therefore it has been supposed that there is some connection between them and the supposed Welsh colony of Madoc. Their houses are of wood and earth. They make rush matting, willow baskets, large beads and black earthen jars. Their canoes are of skin. The dead are wrapped in skins and placed on scaffolds. Later they gather the skulls and place them in circles.

MANDARA, or WANDALA, an African kingdom, capital Doloo, with a population of 30,000 Mohammedan negroes.

MANDAVEE, or MANDIVEE, the principal seaport town of Cutch, India, on the Gulf of Cutch, about 35 miles from Bhooj, or Bhuj. It is fortified, has an open roadstead and an active trade with Sinde, Malabar, the Persian Gulf, Arabia, and the west coast of Africa as far as Zanzibar, besides a large inland trade. Its exports comprise cotton, silk and other piece-goods. Its imports are bullion, ivory, hides, dates, cocoa-nuts, grain and timber. Population, 50,000.

MANDERSON, CHARLES F., United States Senator from Nebraska, born in Philadelphia, Pa., Feb. 9, 1837. He removed to Canton, Ohio, in 1856, and in 1861 entered the army. In 1865 he was brevetted brigadier-general of volunteers for meritorious services during the war. In 1869 he removed to Omaha, where he has since resided and practiced law. He was elected to the United States Senate as a Republican in 1882 and was reëlected in 1888 for the term ending in 1895.

MANDOGARH, or MANDU, a ruined city of India, formerly capital of the Mohammedan kingdom of Malwa, stands 15 miles north of the Nerbudda and 38 southwest of Indore. The ruins stretch for 8 miles along the crest of the Vindhya Mountains, and have a circumference of 37 miles. A deep, narrow valley separates them from the adjoining tableland. The least injured of the ruined buildings is the great mosque, which is reached by a handsome flight of stairs; it is said to be "the finest and largest specimen of Afghan architecture extant in India." There are also a massive royal palace and the white marble mausoleum of the king who raised the city to the acme of its splendor (early 15th century). According to Malcolm, Mandogarh was founded 313 A. D.

MANDVI, the chief seaport of the principality of Cutch, in India, on the north side of the Gulf of Cutch, 36 miles southwest of Bhuj, the capital. It has a good roadstead and a breakwater, but the harbor is choked witn sand. The pilots are in request all through the state. Pop. (1881), 35,980.

MANET, EDOUARD (1832–82), a French painter, the founder of Impressionism: an attempt to avoid such compromises and conventionalities of lighting, composition, etc., as have been frankly accepted by the art of the past, and to render with absolute truth the personal and immediate "impressions" of nature.

MANGAN, JAMES CLARENCE, a gifted Irish poet, born in 1803, died at Meath Hospital, Dublin, June 20, 1849. He was for many years employed in copying in an attorney's office. His heart was framed for suffering, and his whole life was a tragedy of hapless love, poverty and intemperance, until he found rest in death. There is fine quality in his original verse, as well as in his translations from the German, but more especially from the old Irish, as in the impassioned ballad of *Dark Rosaleen*. His *German Anthology* was published in two volumes in 1845, and a complete edition of his poems at New York in 1870, with a biographical introduction by John Mitchel.

MANGANESE. Besides the black and brown oxides of manganese, the "bog manganese" has recently become an article of commerce in the United States. It is found in earthy or kidney-like masses. The bog ore is the common one from Maine to Pennsylvania; whereas from Maryland to Georgia the black ore is the most common one. The latter is mined at the Crimora mine in Augusta county, Va., and the mines of Barton county, Ga. Deposits on Red Rock Island, in San Francisco Bay, are also worked. About 75 per cent. of all the native manganese ore comes from the Crimora mine.

In 1883 Mr. F. R. Mallett discovered a bed of hematite, containing manganese, in the Gasalpur district in India, where there already existed mines very rich in manganese ores. In Coquimbo and Atacama, provinces of Chili, are several manganese mines whose output is very satisfactory, but is seriously interfered with in many places by difficulties of carriage. The most recent mine opened is that of Picanitas in Atacama. The black oxide from Nova Scotia is very valuable for glass-making, because it contains very little iron. It neutralizes the green tint which iron gives to glass. Besides, as a source for oxygen, manganese is now mostly used as an alloy combined with steel (manganese steel), also with copper, for brass and bronze, which are rendered much harder and denser by the addition of manganese. It has been impossible in some cases to separate the manganese and manganiferous ores which are the product of a given mine, but where the total production of a State averages more than 44.25 per cent. of metallic manganese its production is regarded as manganese ores by most metallurgists.

Of late years much attention has been given to the reduction of manganese ore. Charles Bullock repeated the Brunner process of mixing the chloride of manganese with fluor-spar, and reducing it by means of sodium, and found that the product was very brittle, but so hard that the edges would scratch and almost cut glass. After long exposure to the air, it retained its brightness and seemed no more disposed to oxidization than iron. Dr. Glatzel, of Breslau, took dehydrated chloride of man-

ganese, to which he added twice the weight of dry potassium chloride, and fused them at the lowest possible temperature, that they might not volatilize. Then he added, in small quantities, magnesium, in weight about one-sixth that of the manganese chloride, and applied strong heat. Cooling the mass, he broke the crucible and found, after the removal of the foreign matter, a solid block of manganese metal, very hard and of bright luster.

MANHATTAN, a railroad center, a city and the county-seat of Riley county, Kan., situated at the junction of the Big Blue and Kansas Rivers. It has manufactories of boots, shoes, carriages, wagons and cigars. The Kansas State Agricultural College is located here. Population (1890), 3,004.

MANHEIM, a post-borough of Lancaster county, Pa., ten miles northwest of Lancaster, on the Reading and Columbia Railroad. It has manufactories of flour, carriages and lumber. Pop., 2,070.

MANISTEE, a city of Michigan, the terminus of a branch of the Flint Père Marquette Railway. It has several foundries, ten salt-works, and a large number of lumber-mills. Population in 1890, 12,812. See Britannica, Vol. XV, p. 490.

MANISTIQUE, the county-seat of Schoolcraft county, Mich. Pop., 2,940.

MANITOU, a summer-resort at the base of Pike's Peak, Colorado, 6,296 feet above the level of the sea. It is the Saratoga of the West, with soda springs and several large summer hotels. Pop., 1,439.

MANITOWOC, a city of Wisconsin. Population in 1890, 7,710. See Britannica, Vol. XV, p. 491.

MANKATO, a city of Minnesota. Three lines of railway pass here, and small steamboats can ascend the Minnesota River as far as this point. Population, 8,838. See Britannica, Vol. XV, p. 491.

MANLIUS, a post-village of Onondaga county, N. Y., about twelve miles east of Syracuse. It is the seat of St. John's Military School, and contains manufactories of paper, iron, flour, woolen goods and cement.

MANLY, Basil (1798–1868), an American Baptist clergyman. He was ordained in 1822, and then was pastor of churches in Edgefield Court House and Charleston, S. C. From 1837 to 1855 he was president of the University of Alabama and then engaged in missionary travels throughout Alabama.

MANNERS, John James Robert, an English statesman, second son of the fifth Duke of Rutland, born at Belvoir Castle, near Grantham, Leicestershire, in 1818. He took part in the movement for reviving the chivalric spirit of the Middle Ages. In furtherance of this object he published a volume of poems called *England's Trust* (1841), in which the absurd couplet occurs:

> "Let wealth and commerce, law and learning die,
> But leave us still our old nobility."

It expresses the aims of that movement, the advocates of which were known as "Young England." In Parliament he opposed the repeal of the Corn Laws and identified himself with the Conservatives. Under Lord Derby's administration he was first commissioner of works, and under Disraeli he was postmaster-general. In 1888 he succeeded to the dukedom.

MANNING, Daniel, was born at Albany, N. Y., Aug. 16, 1831. Losing his father at an early age he was compelled to support himself, and soon became connected with the "Albany Atlas," a paper afterward merged in the "Albany Argus." Working his way up from office-boy, through the composing-room to the reportorial and editorial staff, by 1873 he had secured control of the paper and had become president of the Argus Publishing Company. On the accession to the Presidency of Mr. Cleveland, in March, 1885, Mr. Manning was appointed Secretary of the Treasury. He held that office until April, 1887, and died Dec. 24, 1887.

MANNING, Henry Edward, an English cardinal, born at Totteridge, Hertfordshire, in 1808. After graduating as double first he was in 1834 appointed rector of Lavington and Graffham in Sussex, and 1840 he was made arch-deacon of Chichester. In 1851 he left the Church of England and joined the Roman Catholic Church. After studying for some years in Rome he was ordained priest in 1857, and founded the congregation of the Oblates of St. Charles Borromeo, at Bayswater, London. On the death of Cardinal Wiseman in 1865 he was appointed archbishop of Westminster. Being a zealous supporter of the Papal infallibility, Dr. Manning was made a cardinal in 1875. He was the foremost spirit in all Catholic movements in England, organized many parochial schools, promoted temperance, started many benevolent societies among the poor, and took a lively interest in all practical reforms. He died Jan. 14, 1892.

MANNING, James (1738–1791), an American clergyman. In 1763 he was ordained to the Baptist ministry, and in 1765 became president of Rhode Island College (now Brown University). He held this position until his death, and from 1771 was also pastor of the First Baptist Church in Providence.

MANNING, Thomas C., born in North Carolina in 1831; died in the city of New York, Oct. 11, 1887. In 1855 he removed to Louisiana. He sat in the Secession convention of that State, and became an officer in a Louisiana regiment. In 1863 he was appointed adjutant-general, with the rank of brigadier-general. For one year he served as associate justice of the supreme court of Louisiana, and in 1877 became chief justice of the supreme court of Louisiana. This office he held for three years, and in 1880 was appointed United States Senator, but was not admitted by the Senate. From 1882 to 1886 he again sat on the supreme bench of the State of Louisiana, was then appointed by Cleveland as minister to Mexico, and filled this office until his death.

MANSARD, or Mansart, François, a distinguished French architect, born at Paris in 1598, died in 1662. He initiated the peculiar roof known by his name.

MANSFIELD, a post-village and a railroad junction of Bristol county, Mass., where cutlery, baskets, gold, shell and horn jewelry are manufactured. The town also contains foundries, spindle-works, and straw-works. Pop., 3,432.

MANSFIELD, a city of Ohio. Population in 1890, 13,473. See Britannica, Vol. XV, p. 498.

MANSFIELD, a post-borough of Tioga county, Pa. It has a State normal school, school for soldiers' orphans, a planing mill, a bedstead factory, and an iron furnace. Pop., 1,762.

MANSFIELD, Edward Deering (1801–1880), an American author. In 1825 he was admitted to the Connecticut bar, and in 1835 became professor of constitutional law in Cincinnati (Ohio) College. He edited the "Cincinnati Chronicle" from 1836 to 1849; the "Atlas," 1849 to 1852; and the "Railroad Record," from 1854 to 1872. He wrote many books on law, mathematics, politics and history.

MANSFIELD, Jared (1759–1830), an American mathematician. From 1777 to 1802 he taught in New Haven and Philadelphia, and then entered the army as captain of engineers. In 1805 he was made major, and in 1808 lieutenant-colonel. From 1803 to 1812 he was United States surveyor of Ohio and the Northwest Territory, and then till 1828 was professor of experimental and natural philoso-

phy in the United States Military Academy. He wrote *Essays, Mathematical and Physical* (1802).

MANSFIELD, Joseph King Fenno (1803–1862), an American soldier. He entered the army in 1822, and was assigned to the engineer corps. In 1832 he became first-lieutenant, and in 1838 captain. He took part in the Mexican war, and received the brevet of colonel for meritorious conduct. In 1853 he was appointed inspector-general of the United States army, and in 1861 was placed in command of the Department of Washington. Later he was assigned to Suffolk, Va., where he acted as military governor. At the battle of Antietam he was mortally wounded. He had previously been promoted major-general of volunteers.

MANSION HOUSE, the official residence of the lord mayor of London, built on the site of the Old Stocks Market, in 1739, at a cost of about $215,000. It is an oblong building, and at its farthest end is the Egyptian Hall. Four hundred guests can dine in this grand banqueting-room, which was designed from the description of an Egyptian chamber given by Vitruvius. All the great banquets, public and private, given by the lord mayor take place here, and there are also fine ball and reception rooms. At the close of the exhibition of 1851 the corporation of London voted $50,000 to be expended on statuary for the adornment of the Mansion House; and there is also a fine gallery of portraits and other pictures. Among its curiosities may be mentioned a state bed which cost $15,000, and a kitchen and culinary utensils extraordinary for their vast size. The Mansion House is often a center of benevolent enterprise in the collection of money for sufferers by war, famine, flood, pestilence, and earthquake abroad, or by colliery explosions, shipwrecks, and lack of employment at home; and Mansion House Funds are also raised for memorials.

MANSUR, Charles, H., born in Philadelphia, March 6, 1835. He went to Missouri in 1856 where he began the practice of law. After receiving several offices at the hands of the Democratic party, in 1872 was the joint nominee for Congress of the Democrats and Liberal Republicans in the tenth district, and was again the nominee of the Democrats in the same district in 1880; was elected to the 50th and 51st Congresses, and reëlected to the 52d Congress.

MANT, Richard, an English prelate, born at Southampton in 1776, died at Ballymony, Ireland, in 1848. He was educated at Oxford, and, after holding curates at Southampton and London, he became successively bishop of Killaloe (1820) and of Down and Connor (1828). He is best known by an *Annotated Bible*, which he prepared in partnership with George D'Oyly. His metrical version of the *Book of Psalms* and *Ancient Hymns of the Roman Breviary* have considerable merit.

MANTES, a town in the French department of Seine-et-Oise, on the left bank of the Seine, thirty-six miles from Paris. It has a fine tower (1344) and a Gothic church, a reduced copy of Notre Dame at Paris. Mantes in 1083 was burned by William the Conqueror, who here received the injury that caused his death. Population, 6,607.

MANTEUFFEL, Edwin Hans Karl, Freiherr Von, a Prussian general and administrator, born at Dresden, Feb. 24, 1809, died at Carlsbad, June 17, 1885. Entering the Prussian Guards in 1827, he rose to be colonel by 1854, and three years later was nominated head of the military bureau at Berlin, a post which he held until 1865. Having been appointed commander of the Prussian troops in Sleswick, he protested against the summoning of the Holstein estates by marching his men into that duchy. On the outbreak of hostilities Manteuffel commanded a division of the army of the Main, which was destined to act against the south German allies of Austria. He took part in the battle of Langensalza, which brought about the capitulation of the Hanover army, and on the 19th of July succeeded Von Falckenstein as commander-in-chief of the Main army, and by winning the battles of Werbach, Taubenbischofsheim, Hemstädt, and Rossbrunn, over the Bavarians and others, he brought that part of the campaign to a successful issue. He entered the war of 1870 as commander of the first corps, but was soon promoted to the command of the first army, which fought successfully at Amiens and other places. Transferred in January, 1871, to the command of the army of the south, operating against Bourbaki, Manteuffel assailed the enemy's rear near Belfort, and drove 80,000 men across the frontier into Switzerland. When peace was proclaimed he was placed at the head of the army of occupation in France, and in 1879 was appointed imperial viceroy of the newly-organized provinces, Alsace-Lorraine.

MANTI, a city, the county-seat of San Pete county, Utah, situated near the center of the State, twenty-three miles southeast of Nephi, in a beautiful and fertile valley. Pop. (1890), 1,950.

MANZANILLA, (1) a port of Mexico, on a fine bay opening to the Pacific, 31 miles by rail west-southwest of Colima. The country around is equally fertile and unhealthy, and the trade is largely in the hands of Germans. Pop., 4,000. (2) A port on the south coast of Cuba, with a good harbor and export trade in valuable woods, sugar, etc. Its climate also is unhealthy. Pop., 8,000.

MAPES, James Jay, born in New York city, May 29, 1806; died there Jan. 10, 1866. In 1832 he invented a new process for sugar-refining. He was appointed professor of chemistry at the National Academy of Design in New York, and delivered lectures on the chemistry of colors; later he became connected with the American Institute in the same capacity. At that time he experimented in many directions, analyzing, distilling, dyeing, etc., and later opened a consultative office for civil engineering. In 1847 he removed from New York city to Newark, where he devoted much attention to agriculture and agricultural chemistry; here he made the first artificial fertilizers, and originated the use of superphosphates in the United States. He was elected president of the Mechanics' Institute in 1844; for many years was vice-president of the American Institute, and delivered many addresses before agricultural societies. In 1840 Professor Mapes published *The American Repertory of Art, Sciences, and Manufactures*, and from 1850–64 *The Working Farmer*.

MAPLE, a tree, the best known species of which is the sugar-maple (*Acer saccharinum*). It is most abundant in the New England States and Canada. Together with the beech, it forms sometimes whole forests. The extraction of the sap does not injure the trees. They yield for many years. To obtain the sap the tree is tapped in February, March or April, according to the locality and the season. Frosty nights followed by warm days favor the flow of the sap. An incision is made in the trunk with an auger or axe, at first ½ inch deep, and is increased by degrees to 2 inches. A tube made of sumach or elder is then inserted ½ inch within the wood. As many as 20 such tubes are sometimes inserted into one tree. The sap flows through these spouts into a trough, whence it is daily conveyed into a large receiver. From this, after being strained, it is carried to a boiler. As it is liable to ferment, the sap cannot be kept long after it is col-

lected. The boiling and refining processes are the same as those in the manufacture of cane-sugar. A single tree yields from two to six pounds of sugar in a season; good vinegar is made from it, and a kind of molasses, called "maple-syrup," which is much superior to that from the sugar-cane. Besides New England, the States of Indiana, Michigan, New York, Ohio and Pennsylvania produce considerable quantities of maple-sugar. The entire product of the United States has reached nearly 35,000,000 of pounds in one year. See Britannica, Vol. XV, pp. 523, 524.

MAQUOKETA, a city, the county-seat of Jackson county, Iowa, in the eastern part of the State, on Maquoketa River, and on the Davenport and St. Paul and the Iowa Midland Railroads.

MARACAYBO, or MARACAIBO, GULF OF, a wide inlet of the Caribbean Sea, extending from the peninsulas of Paraguana and Guajira to the strait by which it is connected with the lake. Its waters are sweet, and deep enough for the largest vessels; but the bar at the mouth, where a swift current runs, makes entrance difficult. The gulf and lake were discovered in 1499 by Ojeda, who found here houses built on piles, and called the district Venezuela ("Little Venice"), which was afterward extended to the entire country.

MARAJO, an island of Brazil, situated between the estuaries of the Amazon and the Para, with an area of nearly 18,000 square miles. It is for the most part low and covered with grass and bush, but in the east and south with dense forest. The soil is fertile, and large herds of cattle are reared in the northeast.

MARATEA, an Italian town of the province of Basilicata. Population, 6,480.

MARATHON, a post-village of Cortland county, N. Y., 50 miles south of Syracuse. It is a shipping point for butter, cheese and live stock. Carriages and cheese-boxes are here manufactured.

MARBECK, or MERBECKE, JOHN, organist of St. George's Chapel, Windsor, was condemned to the stake about 1544 for favoring the Reformation, but pardoned by favor of Bishop Gardiner. In 1550 he published his famous *Booke of Common Praier Noted*, an adaptation of the plain chant of the earlier rituals to the first liturgy of Edward VI. He wrote several theological and controversial works; and a hymn for three voices and parts of a mass by him are extant. He died about 1585.

MARBLE, a limestone or carbonate of lime of many varieties. Pure white marble, without any clouds, streaks or spots, is very scarce in the United States. The best marble quarried in West Rutland, Vt., comes nearest to it. It is used for statuary work. The white marble quarried at Brandon, Vt., is in too thin layers for statuary. Of mottled, clouded and colored marbles there is an abundance in this country. The most beautiful of American colored marbles are those of eastern Tennessee, which are now quite extensively used for ornamental purposes. They have, for instance, been employed in the capitols at Washington, Ohio, Illinois and Iowa, and the Lake Champlain region yields large quantities of colored marble. California has quarries of white marble on the McCloud River, near Copper City. But none has been found yet equal to the Carrara marble for statuary. In 1880 there were 616 quarries being worked in the United States for producing marble and limestone for building purposes. The quantity mined was 66,500,000 cubic feet per annum at a value of $7,000,000. See Britannica, Vol. XV, pp. 528–530.

MARBLEHEAD, a town and port-of-entry of Massachusetts, on a rocky promontory 18 miles northeast of Boston. Population in 1890, 8,200.

MARCEAU, FRANÇOIS SEVERIN DESGRAVIERS (1769–1796), a French general, born at Chartres March 1, 1769. On the outbreak of the revolution he was appointed inspector of the National Guard in his native town, and in 1792 helped to defend Verdun with a body of volunteers till its surrender. Sent to join the Republican army in La Vendee, he was promoted to the rank of general of division. He commanded the right wing at Fleurus, and after the allies retreated occupied Coblenz. During the campaign of 1796 he was given command of the first division of Jourdan's army, and sat down to invest Mainz, Mannheim and Coblenz. But whilst covering the retreat of the French at Altenkirchen he was shot on the 19th of September, and died four days later. His body was buried in the intrenched camp at Coblenz, but was transferred to the Panthéon in Paris in 1889.

MARCET, JANE, born at Geneva in 1785, died in London June 28, 1858. She was the daughter of a rich London merchant, and the author of a popular introduction to chemistry entitled *Conversations on Chemistry*, through which Faraday made his first acquaintance with the subject. She married Alexander Marcet, a Genevan, who settled in London as a physician in the last years of the 18th century, and later in life devoted himself to experimental chemistry. Besides the book on chemistry, she wrote *Conversations on Political Economy*, which was warmly praised by Macaulay.

MARCH, a market-town of Cambridgeshire, from which the Earls of March took their title, is on the Nene, 14 miles east of Peterborough and 16 northwest of Ely. Its church has a fine perpendicular clearstory, with splendid roof. Pop., 6,190.

MARCH, FRANCIS ANDREW, LL.D., born at Millbury, Mass., Oct. 25, 1825; graduated at Amherst College in 1845. In 1858 he was chosen professor of the English language and comparative philology in Lafayette College, Easton, Penn. He has devoted himself specially to the Anglo-Saxon language, ranks among the foremost scholars in that department, and in 1873 was chosen president of the American Philological Association. He is chairman of the committee of that association, appointed in 1874, which is working with a committee of the Philological Society of England for a scholarly and authoritative revision of English spelling. He has also taken the direction, since 1879, of the work in America for the *Historical Dictionary of the English Language* of the Philological Society of England, now in publication by the University of Oxford. He is president of the Spelling Reform Association, councilor of the American Educational Association, vice-president of the New Shakespeare Society and honorary member of the Philological Society of London.

MARCHES, the border districts that run contiguous on each side of the boundary line between England and Scotland, and between England and Wales. The lords of the marches were the nobles to whom estates on the borders were given on condition that they defended the country against the aggressions of the people on the other side. Under the Norman and Plantagenet kings of England there was almost chronic war between the English lords of the marches and the Welsh. The corresponding German word *mark* was in like manner applied to the border countries or districts of the German empire conquered from neighboring nations, as the marks of Austria, of Brandenburg, Altmark, Steiermark, etc.

MARCHETTI, FILIPPO, an operatic composer, born at Rome in 1835, became in 1881 president of a musical college in Rome. His best-known operas are *Romeo e Giuletta* and *Ruy Blas*.

MARCIANISI, an agricultural town of Sicily, situated in a marshy district 12 miles north of Naples. Pop., 11,083.

MARCOU, Jules, a French geologist, born in 1824. In 1846 he was appointed assistant in the mineralogical department of the Sorbonne, and a year later became traveling geologist for the *Jardin des Plantes*. He visited the United States, gathering much important information, and making valuable collections of minerals. In 1853 he entered the United States service and did good work until his health compelled him to return to France. From 1855 to 1859 he was professor of geology in the Polytechnic School at Zürich, but in 1861 returned to the United States and was associated with Louis Agassiz in the foundation of the Museum of Comparative Zoölogy, having charge of the paleontological department till 1864. In 1875 he again entered the United States service. He is the author of several works in geology.

MARCY, Randolph Barnes (1812–1887), an American soldier. He entered the army in 1832, and served in the Black Hawk expedition, on the frontier, in the Mexican war, and in the hostilities against the Seminole Indians. In 1861 he was made brigadier-general and was assigned to inspection duties in the departments of the Northwest, Missouri, Arkansas, Mississippi and the Gulf, until 1865, when he was made inspector-general of the division of the Missouri. From 1869 to 1881 he was inspector-general of the United States army.

MARCY, William Learned, was born at Sturbridge, Mass., Dec. 12, 1786. He graduated at Brown University in 1808. He soon became a leading Democratic politician, and one of the "Albany regency," which was supposed to control the action of the party in New York State. He was United States Senator in 1831–32, and during his term he incidentally made use of the phrase so frequently afterward heard, "To the victors belong the spoils." He resigned to become governor of New York, 1833–39. He was Secretary of War under Polk, 1845–49, and Secretary of State under Pierce, 1853–57. As Secretary of State he conducted with success the Koszta case in 1854, involving a collision with Austria on the subject of the right of expatriation. All his political leanings were to that branch of the Democratic party in New York which made the strength of the new Republican party in 1856, and he would have been its natural leader if he had followed his own convictions on the Kansas-Nebraska bill. He hesitated, and other men took his place. He died at Ballston Spa, N. Y., July 4, 1857.

MARDI GRAS, a festival proceeding the first day of Lent, or Ash Wednesday; specially observed in New Orleans, and familiarly called "Fat Tuesday;" signified by a unique and gorgeous procession under the direction of "King Carnival."

MARENGO, a manufacturing town of Illinois, about 65 miles northwest of Chicago. It is the trade-center of a rich agricultural district. Pop., 1,445.

MARENGO, a manufacturing town, the county-seat of Iowa county, Iowa. It is well situated in the midst of an excellent farming and grazing region. Pop., 1,710.

MAREY, Étienne Jules, a French physiologist, born at Beaune, in the department of Côte-d'Or, France, in 1830. He studied medicine at Paris, obtaining his degree in 1859. In 1867 he was made professor of natural history in the Collége de France. Dr. Marey has invented several instruments for recording the movements of the heart, lungs, arteries, muscles and other parts of the human body, and made many experiments with them. He has written *Physiologie médicale de la circulation du sang; Du Mouvement dans les fonctions de la vie; La Machine Animals*, of which an English translation has appeared in New York in 1874 under the title *Animal Mechanism; Physiologie expérimentale* (1875), and *La Méthode graphique dans les Sciences expérimentales* (1878).

MARGRY, Pierre, a French historian, born at Paris in 1818. Being one of the archive-keepers of the marine department he was in 1842 commissioned to make researches regarding French expeditions to America.

MARHEINEKE, Philipp Conrad, a Protestant theologian, born at Hildesheim, May 1, 1780, died May 31, 1846. He began to teach at Göttingen in 1804, was appointed a theological professor and university preacher at Erlangen in 1805, and subsequently held theological chairs in Heidelberg and Berlin. After Hegel's death Marheineke was the chief figure among the right wing of that philosopher's disciples.

MARIA CHRISTINA, Queen of Spain, born at Naples in 1806, died at Ste. Adresse, near Havre, in 1878. She was the second daughter of King Francis I. of Naples. In 1829 she became the fourth wife of King Ferdinand VII. of Spain. She bore two daughters, one of whom was the future Queen Isabella II. The king died in 1833 after declaring the crown inheritable in the female line and appointing the queen as regent in his will. After three months she married a soldier of the royal guard named Muñoz. In 1840 she abolished the municipal liberties of Spain. This produced a general insurrection, which compelled her to abdicate in favor of Marshal Espartero as regent. She retired to Paris. When Isabella was declared of age, in 1843, Christina returned to Madrid, took part in public affairs, and was ten years afterwards again driven from Spain. After September, 1864, she again resided in Madrid for four years. She was then driven out of the country in company with her daughter Isabella.

MARIANNA, an episcopal city of Brazil, three miles east of Ouro Preto. The neighboring gold-mines are exhausted. Pop., 5,000.

MARIANNA, the county seat of Jackson county, Fla. Pop., 1,926.

MARIANNA, the county seat of Lee county, Ark. Pop., 1,126.

MARIE GALANTE, a French Island in the West Indies, discovered by Columbus in 1493. It lies 17 miles southeast of Guadeloupe. Its area is 58 square miles. Pop., 15,000.

MARIENWERDER, a town of West Prussia, picturesquely situated three miles east of the Vistula and 55 miles by rail south of Danzig. It was founded in 1233 by the Teutonic Knights, and has an old castle and a domkirche. Pop., 8,079.

MARIETTA, a prosperous manufacturing town, the county-seat of Cobb county, Ga. It is the seat of several educational institutions. Kenesaw Mountain is about two miles distant. Population in 1890, 3,384.

MARIETTA, a city of Ohio, the oldest town in the State. It has varied manufactures, and remarkable traces of the mound-builders. Population in 1890, 8,273. See Britannica, Vol. XV, p. 542.

MARIETTA, a post-borough of Lancaster county, Pa., on the Susquehanna River and on the Columbia branch of the Pennsylvania Railroad, 25 miles southeast of Harrisburg. It has rolling mills, furnaces, large hollow-ware and enameling works and lumber mills. It is a market for lumber. Population, 12,402.

MARINE CITY, a post-village of St. Clair

county, Mich., seven miles below St. Clair, on St. Clair River. Salt is found here and ship-building is an important industry of the town. Pop., 3,268.

MARINE HOSPITAL SERVICE. This is the medical bureau of the United States Treasury Department, which is charged with the duty of providing relief for the sick and disabled seamen and employés of the United States merchant marine, the management of the national quarantine, examination of the United States merchant marine pilots for color-blindness, examination of officers and men of the United States revenue cutter service as to physical condition, examination of cadets of that service as to their fitness for appointment, physical examination of surfmen of the life-saving service as to their ability to perform the duties assigned them, and the physical examination of officers and crew of any United States merchant vessel whose master desires such examination. In 1870 an act of Congress was passed that reorganized this service, increased the tax on seamen to forty cents per month, and authorized the Secretary of the Treasury to appoint a "supervising surgeon" to manage all business connected with this service. In 1875 the title of supervising surgeon was changed by act of Congress to "supervising surgeon-general," and the appointment made a Presidential one. In 1884 the monthly tax on seamen was abolished, and a tonnage tax substituted, which is now supplemented by a small annual appropriation.

Since the reorganization of the service in 1871, the surgeon-general has made annual reports to the Secretary of the Treasury, which give detailed statements of the operation of the service, describe interesting cases of diseases and injuries, and give other valuable information, especially in regard to quarantine, hygiene, hospital instruction, etc. The medical corps of the service consists of a supervising surgeon-general, a number of hospital surgeons, passed assistant surgeons and assistant surgeons. Hospital stewards are assigned to duty at all the marine hospitals and larger stations, and are graded into three classes, according to efficiency. Acting assistant surgeons are on duty at stations where there are no marine hospitals, and where but few seamen apply for relief.

MARINE LEAGUE, a distance of three miles generally acknowledged as the shore distance over which the nations severally may have exclusive right upon the sea water abutting against their respective coasts. With respect to the limitation of jurisdiction on the sea coast their are two principles universally admitted—first, that the sea is open to all nations; and second, that there is a portion adjacent to every nation over which the sovereignty of that nation may rightly extend to the seclusion of every other political claim.

It is difficult in many cases to define the limits of these waters.* Such portions as harbors and waters above low-water mark are recognized as within the *lex loci*, and those persons on board of ships are subject to the local laws and regulations as fully as if they were residing on the land. With reference to parts more seaward, the question is more complicated. The cannon-shot limit is the popular rule: "*Finitur terræ dominium ubi finitur armorum vis.*" For all practical purposes this is the marine league of three miles. The United States and Great Britain have agreed to this claim as between themselves, but other nations have not. Norway specified in one case four miles, England six miles under an act of George IV., and again twelve miles under the "Hovering Acts." The United States in 1875 claimed the same for revenue purposes, and even as far as the Gulf Stream for the exclusion of belligerents. Spain claimed a six-mile belt around Cuba. Great Britain has been granted by China jurisdiction over British subjects on vessels up to one hundred miles from the coast of China. The question of jurisdiction over bays has been much disputed. St. George's Channel has been diplomatically acknowledged to be British territory, and the Bay of Newfoundland has been legislated for as if British territory. Generally speaking, however, the three-mile limit is acknowledged as the limit. Foreigners *have a right of use over such waters subject to definite limitations.* Belligerent acts must not be carried on there; piracy and smuggling can be stopped, and quarantine regulations enforced. The one general rule is that the state may exercise any rights over these waters in defense of herself and her own interest, or in maintaining the right of free passage to all others. It is commonly acknowledged that the "fructus" of the waters belongs to the country, but much difference of opinion exists as to how the nations are to be protected in its enjoyment.

The most conspicuous illustrations of the principle of free navigation of inland seas are to be found in the opening up of the Sea of Marmora and the Black Sea, and in the liberation of the Sound from the toll formerly collected by Denmark—which, as a kind of concession to a small state without enemies, was effected in 1857 by a payment from the European powers of a sum approaching to three and a half millions of pounds sterling. The principle of free navigation has been still further advanced, so as to include navigable rivers. The Congress of Vienna claimed freedom for rivers bordering or separating several states; and first the Rhine, then the Scheldt, Meuse, Po, Vistula, and other rivers were freed from toll and prohibition. The Danube was not liberated until 1856.

From navigation it is but an advance of principle to the other channels of intercommunication. Much remains to be achieved in regard to international railway lines, postal and telegraphic services, and possibly an international free press. In the meantime something has been done by the Postal Union, and the various telegraphic treaties and conventions, to prepare the way for a more liberal and harmonious system.

MARINE STORE, in England, a place for the buying and selling of old ship's materials.

MARINETTE, the county-seat of Marinette county, Wis., at the mouth of the Menomonee River. The chief business is lumbering. The town contains saw and planing mills, also iron-works. Pop., 11,523.

MARINO, a town on the Alban Hills, twelve miles southeast of Rome. It has a castle belonging to the Colonnas, who took it from their rivals, the Orsinis, in 1424, and a cathedral and churches with pictures by Guido, Domenichino and Guercino. It produces wine and has manufactories of soap, leather, etc.

MARINO, or San Marino, one of the most ancient and most limited republican states of Europe, consists of a craggy mountain 2,200 feet in height, in the Apennines, and encircled by provinces formerly belonging to the Pontifical States. Its total area is 32 miles, and it comprises a town of the same name, and several villages. In 1872 it concluded a treaty of protective friendship with Italy. Population, about 8,000.

MARIO, Giuseppe, a famous Italian tenor, by birth the Caviliere di Candia and son of General di Candia, born at Cagliari in 1810, died at Rome, Dec. 11, 1883. He served in the army for some years, but

*See *Government Year Book*, edited by Lewis Sargent, 1889; also *Commentaries on International Law*, by Sir Robert Fillmore.

a youthful escapade led to his forsaking Italy for Paris, where he quickly won his way into the most exclusive circles, both by the charm of his manners and his exquisite voice. Having contracted debts, however, he accepted the appointment of first tenor of the opera, with a salary of 1,500 francs per month, changing his name at the same time from De Candia to Mario. He made his debut as "Robert" in *Robert le Diable*, and achieved the first of a long series of operatic triumphs in Paris, London, St. Petersburg and America. By the famous singer, Giulia Grisi, he was the father of six daughters. In his later years he lost his fortune through disastrous speculations. In May, 1878, a benefit concert in London yielded him as much as $5,000.

MARION, the county-seat of Perry county, Ala. It has railroad repair-shops, carriage-factory, two colleges and two female seminaries. Pop., 1,982.

MARION, a railroad center and the county-seat of Linn county, Ia. It contains factories and mills for the manufacture of lint, flour, beer, carriages, furniture and farm-implements. Pop., 3,094.

MARION, a railroad center and county-seat of Grant county, Ind. It contains wood-working factories, flax factories, a foundry, and flour-mills. Pop., 8,769.

MARION, or MARION CENTRE, a city, the county-seat of Marion county, Kan., situated near the center of the State, about fifty miles west of Emporia. Pop., 2,047.

MARION, a railroad center and county-seat of Marion county, Ohio, forty miles north of Columbus. It contains grain elevators, machine-shops, and manufactories of carriages, wagons, rakes, and chains. Pop., 8,327.

MARKHAM, CLEMENTS ROBERT, C.B., F.R.S., F.S.A., geographer and author, son of the Rev. D. Markham, canon of Windsor, born at Stillingfleet, England, in 1830, educated at Westminster, and entered the navy in 1844. In 1851 he left the navy, and in 1855 became a clerk in the board of control. In 1863 he was elected secretary of the Royal Geographical Society, and in 1867 became assistant secretary in the India office. In 1868 he was placed in charge of the geographical department in that office. He served in the Arctic expedition in search of Sir John Franklin. He explored Peru and the forests of the Eastern Andes; he introduced the cultivation of the cinchona plant from South America into India; served as geographer in the Abyssinian expedition, and was present at the storming of Magdala. His numerous publications include many translations from the Spanish, and several antiquarian and genealogical works. He edited the "Geographical Magazine" from 1872 to 1878.

MARKS, HENRY STACEY, R.A., was born in London, Sept. 13, 1829. He gained admission as a student to the Royal Academy in 1851. He was elected an associate of the Royal Academy in January, 1871; an associate of the Water Color Society in March the same year; and a royal academician Dec. 19, 1878. Mr. Marks, whose *forte* is genre and quaint mediævalism, has been a constant exhibitor at the Royal Academy since 1853.

MARMADUKE, JOHN S., born in Missouri, March 14, 1833; graduated from West Point in 1857, and served in Utah and New Mexico under Albert Sidney Johnston. Like his general he joined the Confederacy, and was made colonel of the 3d Confederate infantry. He fought with gallantry at Shiloh, and was wounded in the second day's fight. Afterward he took part in the campaigns of Mississippi and Arkansas, and was made a major-general for his services against N. P. Banks. He was captured in Missouri, in October, 1864, and held a prisoner of war at Fort Warren, Boston, until August, 1865. In 1875 he was appointed railway commissioner, and in 1884 was elected governor of Missouri. He died in 1887.

MARMORA, ALFONSO FERRERO DELLA, born in Turin, Italy, in 1804; became Sardinian minister of war in November, 1848, and held that office until February, 1855. A year later he commanded the Sardinian contingent in the Crimea, and on his return home again served as minister of war. In July, 1859, he became president of the council of ministers, which office he held for one year. In 1864 he was again president, and also held the portfolio of foreign affairs. When the Austro-Prussian war broke out in June, 1866, Della Marmora resigned his offices to take command of the army. His troops were overwhelmed by the Archduke Albert of Austria, at Custozza, a few weeks later. Della Marmora practically disappeared from public life after this and died at Florence, Jan. 8, 1878.

MAROCHETTI, CHARLES (BARON), was born at Turin, Italy, 1805, and removed to England, in 1848. He had already produced numerous statutes, busts, and other works of sculpture, and in England his chief works are the colossal statue of Richard, Cœur de Lion, in Palace Yard, Westminster, the equestrian statue of Queen Victoria at Glasgow, and various groups of statuary in London. He became a royal academician in 1866, and died in December of the following year.

MARRIAGE IN THE UNITED STATES. For article on the general subject of MARRIAGE, see Britannica, Vol. XV, pp. 565–69. Marriage as defined in statutes and courts of the United States is first, the legal union of a man with a woman for life; and, secondly, a mutual agreement formally declared, by which a man and a woman of the proper respective ages and conditions join one another in wedlock. As far as the parties themselves are concerned, it is a civil "contract" implying free consent on both sides; and as far as the State is concerned, the parties must have certain qualities with respect to age, mutual relationship, and freedom from any previous connection. The State sees to it that the contract is not rescinded either by mutual consent nor one-sidedly; because interests of the State and of the children, if there are any, require the affixing of certain permanent duties and obligations upon the contracting parties.

In most of the United States marriage does not require any special formalities. If a man and a woman promise and agree by word of mouth to take each other as husband and wife, the contract and the resulting legal status of marriage are perfected. Their marriage is valid. Such is the decision of the highest courts. Solemnization by a clergyman, or by a civil magistrate, the presence of witnesses, and all the ceremonies usually observed on such occasions, even those provided for by statute, are only means to perpetuate the evidence of the contract made between the two spouses, which itself constitutes the marriage. These ceremonies are not in the least essential to the efficacy of the contract. In States where a license, public notice ("bann"), or other preliminary steps are prescribed by statute, a failure to comply with these provisions does not impair the marriage if it has been contracted without their presence. It merely subjects the delinquent parties to a penalty. The words of the contract by which the parties take each other as husband and wife, must be of present force and operation (*in presenti*). If they are only mutual promises of a future force and operation (*in futuro*), it is held in New York and several other States that no marriage arises, even if it is followed by immediate cohabitation.

## EPITOME OF STATUTES RELATING TO MARRIAGE.

The subjoined table presents, in brief and convenient form, an epitome of the statutes of the different States and Territories of the United States relating to marriage. The interested reader will do well to consult, on any mooted question which may arise, the special requirements of the latest laws and court decisions relating to marriage in the particular State in which the question is raised:

| States. | Minimum Age Required. | | Degrees of Consanguinity Prohibited. | Marriage Voided by | Marriage Voidable. | Is license required? (d) | Age Entitled to License Without Parents' Consent. | |
|---|---|---|---|---|---|---|---|---|
| | Male. | Fem'e. | | | | | Male. | Fem'e. |
| Alabama | 17 | 14 | Ancestors, descendants; also brothers, sisters, uncles, aunts, nephews, nieces, step-relatives. | Prohibited degrees; white with negro blood; under age of consent. | | Yes | (f) 21 | 18 |
| Arizona | 18 | 16 | Ancestors, descendants; also brothers, sisters, uncles, aunts, nephews, nieces, first cousins. | Prohibited degrees; white with negro or Mongolian; under age of consent. | | Yes | (g) 18 | (g) 16 |
| Arkansas | 17 | 14 | Same as Arizona | Prohibited degrees; bigamous; under age of consent; white with negro blood. | Insanity; incapacity; consent obtained by fraud or force (h). | Yes | 21 | 18 |
| California | 18 | 15 | Ancestors, descendants; also brothers, sisters, uncles, aunts, nephews, nieces. | Prohibited degrees; bigamous; white with negro blood. | Under age of consent if no cohabitation since attaining such age; insane or idiot; incapacity; force or fraud if no voluntary cohabitation; bigamy. | Yes | 21 | 18 |
| Colorado | (a) 14 | 12 | Same as California | Same as California | | Yes | 21 | 18 |
| Connecticut | (a) 14 | 12 | Same as Alabama | Prohibited degrees | | Yes | 21 | 21 |
| Dakota (i) | 18 | 15 | Same as Arizona | Prohibited degrees; bigamous. | Same as California | | 18 | 15 |
| Delaware | (a) 14 | 12 | Same as Alabama, and great nephews and nieces. | Same as California | Insane or idiot | Yes | 21 | 18 |
| Dist. of Col'bia | (a) 14 | 12 | Same as Maryland | Same as Maryland | | Yes | .. | .. |
| Florida | (a) 14 | 12 | "Within the Levitical degrees." | Bigamous; white with negro blood. | | Yes | 21 | 21 |
| Georgia | 17 | 14 | "Within the Levitical degrees," and step relatives. | Prohibited degrees; bigamous; insane when married; physically incompetent; white with negro blood; force or fraud. | | Yes | 21 | 18 |
| Idaho | 18 | 16 | Same as California | Same as California | Same as California | | 18 | 16 |
| Illinois | 17 | 14 | Same as Arizona | Prohibited degrees; insane when married | | Yes | 21 | 18 |
| Indiana | 18 | 16 | Same as Arizona | Same as California; insane when married | Under age of consent; insane or idiot. | Yes | 21 | 1. |
| Iowa | 16 | 14 | Same as Alabama | Same as Dakota | Same as Indiana | Yes | 21 | 1 |
| Kansas | 15 | 12 | Same as Arizona | Prohibited degrees | Same as Indiana | Yes | .. | .. |
| Kentucky | 14 | 12 | Same as Delaware | Prohibited degrees; bigamous; under age of consent; insane when married; physically incompetent; white with negro blood. | Under age of consent if no cohabitation since attaining age; consent obtained by fraud or force. | Yes | 21 | .. |
| Louisiana | 14 | 12 | Same as California | Bigamous | Consent obtained by fraud or force if no cohabitation before suit; mistake in person. | Yes | 21 | 21 |
| Maine | (a) 14 | 12 | Same as Alabama | Prohibited degrees; bigamous; insane when married; imprisonment for life. | | Yes | 21 | 18 |
| Maryland | (a) 14 | (c) 12 | Same as Alabama | Same as California | | Yes | (g) 21 | (g) 16 |
| Massachusetts | (a) 14 | 12 | Same as Alabama | Prohibited degrees; bigamous; under age of consent without cohabitation; insane when married. | | Yes | 21 | 18 |
| Michigan | 18 | 16 | Same as Alabama | Same as Mass.; imprisonment for life; force or fraud. | Same as California | Yes | .. | .. |
| Minnesota | 18 | 15 | Same as California | Prohibited degrees bigamous; under age of consent. | Under age of consent if no cohabitation since attaining such age; insane; force or fraud. | Yes | 21 | 18 |

| Wyoming | 18 | 16 | Same as Arizona | Prohibited degrees; bigamous; insane when married. | Same as Indiana, and under age of consent; force, and fraud if parties have not cohabited since. | Yes | 21 | 18 |

(*a*) As at common law; no statutory mention. (*b*) Consent of parents required if under age. (*c*) Consent of parents required by females under sixteen. (*d*) A marriage without a license is nevertheless valid; the person solemnizing it is punished. (*e*) Without parental consent. (*f*) Parties under 21 years must give $200 bonds that no lawful impediment exists. (*g*) Unless parents consent to less, but not under age of consent. (*h*) Forced marriage is punishable by death to the male participant. (*i*) Under territorial laws.

For information as to the State laws relative to divorces, see that topic in these Revisions and Additions.

MARRYAT, Florence, was born at Brighton in Sussex, and educated at home. She began to write in 1865, when her first novel, *Love's Conflict*, was published, since which time she has written forty-three works, most of which have been republished in America and Germany, and translated into French, German, Russian, Flemish, and Swedish. She was appointed editor of "London Society" in 1872, and has been a constant contributor to magazines and newspapers. She is known on the stage as an operatic singer and high-class comedy actress, and has been most successful as an entertainer and lecturer.

MARSEILLES, a thriving town of Illinois, situated on the north bank of the Illinois River, about eighty miles southwest of Chicago. It has an excellent water-power, and manufactories of paper, flour, and agricultural implements. Pop., 3,542.

MARSH, George Perkins, born in Woodstock, Vt., March 15, 1801; died in Vallombrosa, Italy, July 23, 1882. He was graduated at Dartmouth in 1820, and studied law in Burlington, Vt. In 1835 he was chosen a member of the State legislature, and in 1842 elected to Congress on the Whig ticket, where he served until 1849. From 1849 until 1853 he served as United States minister to Turkey, and in 1861 was appointed minister to Italy, which position he held until his death. He received the degree of LL.D. from several colleges, and was connected with many learned societies. He rendered important services as a philologist, and made the Gothic dialects his particular study. In 1858 and 1859 he lectured on language at Columbia College and the Lowell Institute. His works on the language and literature of early England are of the highest value.

MARSH, Othniel Charles, an American naturalist, born in 1831. In 1866 he became professor of paleontology at Yale, which position he still holds. He has since devoted himself to the original investigation of extinct vertebrate animals, and in his various explorations above 1,000 new species have been brought to light. He has published descriptions of more than 300 of the more important ones. Prof. Marsh is a member of numerous scientific societies.

MARSHALL, the county-seat of Clark county, Ill. It is a railroad junction and contains flour mills. Pop., 1,900.

MARSHALL, a city, the county-seat of Calhoun county, Mich., on the Michigan Central Railroad. Pop., 3,968.

MARSHALL, the county-seat of Saline county, Mo., sixteen miles west of the Mississippi River, in a fine agricultural region where anthracite coal abounds. Pop., 4,297.

MARSHALL, a town, the county-seat of Harrison county, Texas, at the junction of three railroads. The town has several foundries, car-wheel works, railway machine-shops, and a good trade in cotton and other products. Population in 1890, 7,207.

MARSHALL, Herbert Menzies, was born at Leeds, England, Aug. 1, 1841, and educated at Westminster School, and at Trinity College, Cambridge, where he graduated in 1864, second class in the natural science tripos. In the same year he went to Paris for the purpose of studying architecture. In 1871 he exhibited his first drawing at the Dudley Gallery. In 1879 he was elected an associate of the Society of Painters in Water Colors, and became full member in 1882.

MARSHALL, Humphrey, born in Frankfort, Ky., Jan. 13, 1812; graduated at West Point in 1832, but resigned to become a lawyer. He was sent to Congress twice from his native State, served as colonel of cavalry in the Mexican war, and in 1861 entered the Confederate service, in which he served throughout the war, rising to the rank of major-general. He died at Louisville, March 28, 1872.

MARSHALL, Thomas Alexander (1794–1871), an American jurist. He began the practice of law in Frankfort, Ky., and in 1819 removed to Paris, Ky. In 1827–28 he was a member of the legislature, and from 1831 to 1835 was in Congress. From 1835 to 1856 he was judge of the court of appeals, and from 1836 to 1849 was professor in the law school of Transylvania. In 1866-67 he was chief justice of the court of appeals.

MARSHALL, Thomas Francis (1801–1864), an American lawyer. He began the study of law in Versailles, Ky., and from 1832 to 1836, and again in 1838 to 1839, he was a member of the legislature; from 1841 to 1843 he was a member of Congress, and in 1849 raised a company of cavalry and served in the Mexican war. His last years were devoted to the study of geology and history.

MARSHALL, William Calder, a Scotch sculptor, born at Edinburgh in 1813. After studying art in Edinburgh, London, and Rome, he settled in London in 1839, was elected an associate of the Royal Academy in 1844 and an academician in 1852. He devoted himself chiefly to poetic sculpture.

MARSHALLTOWN, a city of Iowa, finely situated on high ground. It has a high-school, railway shops, flour and oil mills, foundries, large grain elevators, and two factories for making steel fencing-wire. Its trade in wheat and flour is considerable. Population, in 1880, 6,240; in 1890, 8,914. See Britannica, Vol. XV, p. 574.

MARSHFIELD, a city of Wood county, Wis., having large lumber manufactories. Pop., 3,450.

MARSIVAN, a town of Asia Minor, in the vilayet of Sivas, twenty-three miles northwest of Amasia, with a silver mine. Pop., 11,000.

MARSTON, Philip Bourke, poet, the son of Dr. Westland Marston, was born in London, Aug. 13, 1850. After contributing a few poems to the "Cornhill Magazine" and other periodicals, he published his first volume of poems, entitled *Song Tide*, in 1870. This was followed by a second volume, entitled *All in All*, in 1875, and by a third, entitled *Wind Voices*, 1883. These poems gained for him the friendship of Swinburne, and of the late Dante Gabriel Rossetti, who addressed to him a sonnet. Mr. Marston has contributed poetical criticisms, essays, and novelettes to various well-known periodicals both in England and America.

MARSTON, Westland, dramatic poet, born at Boston, England, Jan. 30, 1820, died in London, Jan. 5, 1890. In 1842 his *Patrician's Daughter*, a blank verse tragedy of the day, was brought out at Drury Lane by Macready. It was the first, and also the most successful, of more than a dozen plays. A collective edition of them and his poetical works appeared in two volumes in 1876. Besides these, he wrote a novel, a good book, on *Our Recent Actors*, and a mass of poetic criticism.

MARTELLO TOWERS, solid round towers for coast defense, about 40 feet high, situated on the beach. They were so called because at Mortello Point, in Corsica, a small round tower stood admirably an immense cannonade from an English fleet under Lord Hood in 1794. They were mostly erected at the end of the eighteenth century as a defense against French invasion, and are now regarded as obsolete.

MARTENSEN, Hans Lassen (1808–1884), a Danish theologian, born at Flensburg, in 1808. He studied at the universities of Copenhagen, Berlin, Vienna, Munich, and Paris, and was made professor of philosophy at Copenhagen in 1840, but afterwards transferred to the department of theology. In 1845

he became court-preacher, and in 1853 was made bishop of Zealand. In 1840 he published a valuable monograph on *Meister Eckhart*, the German mystic, and nine years later laid the foundation of a European fame by a masterly work, from the conservative Lutheran standpoint, on *Christian Dogmatics*.

MARTIAL LAW, the exercise of arbitrary power by the military authorities of a district or country wherein the ordinary administration has ceased to be operative either on account of civil disturbance or because of the presence therein of a hostile force. It is not the same as "military law." The latter is the law which governs the army and soldiers at all times, but affects civilians only when they accompany a military force on active service. Martial law is, in fact, no law at all, but simply the will of the supreme authority. No rules can be laid down for its application. The regulations of the United States army give some of the conditions under which martial law may be exercised and by which its functions are limited.

1. "A place, district, or country occupied by an enemy stands, in consequence of the occupation, under the martial law of the invading or occupying army, whether any proclamation declaring martial law, or any public warning to the inhabitants has been issued or not. Martial law is the immediate and direct effect and consequence of occupation or conquest. The presence of a hostile army proclaims its martial laws.

2. "Martial law does not cease during the hostile occupation, except by special proclamation, ordered by the commander-in-chief; or by special mention in the treaty of peace concluding the war, when the occupation of a place or territory continues beyond the conclusion of peace as one of the conditions of the same.

3. "Martial law in a hostile country consists in the suspension, by the occupying military authority, of the criminal and civil law, and of the domestic administration and government in the occupied place or territory, and in the substitution of military rule and force for the same, as well as in the dictation of general laws, as far as military necessity requires this suspension, substitution, or dictation. The commander of the forces may proclaim that the administration of all civil and penal law shall continue, either wholly or in part, as in times of peace, unless otherwise ordered by the military authority.

4. "Military oppression is not martial law; it is the abuse of the power which that law confers. As martial law is executed by a military force, it is incumbent upon those who administer it to be strictly guided by the principles of justice, honor and humanity—virtues adorning a soldier even more than other men, for the very reason that he possesses the power of his arms against the unarmed.

5. "Martial law should be less stringent in places and countries fully occupied and fairly conquered. Much greater severity may be exercised in places or regions where actual hostilities exist, or are expected and must be prepared for. Its most complete sway is allowed—even in the commander's own country—when face to face with the enemy, because of the absolute necessities of the case, and of the paramount duty to defend the country against invasion. To save the country is paramount to all other considerations.

6. "All civil and penal law shall continue to take its usual course in the enemy's places and territories under martial law, unless interrupted or stopped by order of the occupying military power; but all the functions of the hostile government—legislative, executive, or administrative—whether of a general, provincial, or local character, cease under martial law, or continue only with the sanction, or if deemed necessary, the participation of the occupier or invader.

7. "Martial law extends to property, and to persons, whether they are subjects of the enemy or aliens to that government.

8. "Consuls, among American and European nations, are not diplomatic agents. Nevertheless, their offices and persons will be subjected to martial law in cases of urgent necessity only; their property and business are not exempted. Any delinquency they commit against the established military rule may be punished as in the case of any other inhabitant, and such punishment furnishes no reasonable ground for international complaint.

9. "The functions of ambassadors, ministers, or other diplomatic agents, accredited by neutral powers to the hostile government, cease, so far as regards the displaced government; but the conquering or occupying power usually recognizes them as temporarily accredited to itself.

10. "Martial law affects chiefly the police and collection of public revenue and taxes, whether imposed by the expelled government or by the invader, and refers mainly to the support and efficiency of the army, its safety, and the safety of its operations.

11. "The law of war (martial) does not only disclaim all cruelty and bad faith concerning engagements concluded with the enemy during the war, but also the breaking of stipulations solemnly contracted by the belligerents in time of peace, and avowedly intended to remain in force in case of war between the contracting powers. It disclaims all extortions and other transactions for individual gain; all acts of private revenge, or connivance at such acts. Offenses to the contrary shall be severely punished, and especially so if committed by officers.

12. "Whenever feasible, martial law is carried out in cases of individual offenders by military courts; but sentences of death shall be executed only with the approval of the chief executive, provided the urgency of the case does not require a speedier execution, and then only with the approval of the chief commander."

In the United States, in time of peace, martial law must be declared by proclamation by the executive of the State or Territory, or by the President of the United States, if there is a riot, insurrection or other disturbance. It is limited to the extent of the disturbed territory and the executive jurisdiction under the laws.

MARTIGNY LA VILLE, a town of Switzerland, canton of Valais, seventeen miles southwest of Sion, on the Dranse. Pop., 1,490.

MARTIN, Benjamin Nicholas, born in Mt. Holly, N. J., Oct. 20, 1816; died in New York city, December 16, 1883. He was graduated at Yale in 1837, filled pulpits in New York city and in the interior cities of the State, and in 1852 became professor and lecturer in the University of the City of New York, where he remained for thirty-one years.

MARTIN, Bon Louis Henri, a French historian, born at St. Quèntin, Feb. 20, 1810, died at Paris, Dec. 14, 1883. He wrote dramas and historical novels for awhile; but about 1830 he gave himself up to the writing of history, joining Paul Lacroix, "Bibliophile Jacob," in his vast project for a history of France in 48 volumes, consisting of extracts from historians and chronicles from the earliest period to 1830. He published the first volume in 1833, and thenceforward toiled alone at the vast undertaking, which was completed on a smaller scale in 1836. He now set himself to a still more gigantic task, his great *Histoire de France*. A third and much improved edition earned the Gobert prize; the fourth edition was awarded, by the Institution in 1869, the great prize of 20,000 francs. This magnificent work comes down only to 1789; its continuation to the author's own time formed the less admirable *Histoire de France Moderne*. Martin acted for a time as maire of one of the arrondissements of Paris; and was chosen deputy for Aisne in 1871, senator in 1876. He was elected a member of the French Academy in 1878. He wrote several minor histories, such as the *Histoire de Soissons; Daniel Manin*, and *Jeanne d'Arc*. Martin was the last of the giants of French history influenced by Augustin Thierry, who aimed at comprehending the whole field within their range of study. The whole work reveals impartiality and insight, is excellently arranged, and admirably written—the work of a true patriot, and if a Chauvinist, a Chauvinist of genius. It is beyond doubt the best work dealing in detail with the history of France.

MARTIN, Felix, a Canadian author, born in France in 1804. He was sent to Canada in 1842 as a Jesuit missionary, and was stationed first at Montreal, then at Quebec. Afterwards he returned to France, and connected himself with a Jesuit establishment near Paris. He has written several works of importance.

MARTIN, François Xavier (1764–1846), an American jurist. He was admitted to the bar in New Berne, N. C., in 1789, and in 1806–7 was a member of the legislature. In 1809 he became United States judge for the territory of Mississippi, and in 1810 of Orleans. In 1813 he was made attorney-general of Louisiana, and in 1815 judge of the supreme court. In 1835 he became chief justice,

and in 1846 retired. He wrote several works on law and history.

MARTIN, Lady (Helen Faucit), born in 1816; went upon the stage in 1836, and speedily took rank as an artist of the very first class. She married Sir Theodore Martin in 1851 and retired from the stage, but has since, on several occasions, given readings from Shakespeare and other great dramatists for the benefit of charities. In 1885 she published her studies *On Some of Shakespeare's Female Characters*.

MARTIN, Henry Newell, born in Ireland in 1848, studied at University College, London, and took his B.A. degree at Cambridge, England, where he became a fellow of his college and lecturer on natural history. In 1876 he was invited to become professor of biology in the newly-constituted Johns Hopkins University at Baltimore, which position he has since retained. Prof. Martin is a member of many scientific societies and a fellow of the Royal Society of England, and has contributed largely to scientific journals, his special subject being biological research.

MARTIN, Luther (1748–1826), an American lawyer. In 1771 he was admitted to the bar, and settled in Somerset, Md., where he attained a large practice. In 1778 he was appointed attorney-general of Maryland, resigning in 1805. From 1814 to 1816 he was chief judge of the court of oyer and terminer in Baltimore, and from 1818 to 1820 was again attorney-general. In 1804 he appeared as counsel for the defense in the impeachment of Samuel Chase before the United States Senate, and in 1807 as counsel for Aaron Burr at Richmond.

MARTIN, Sir Theodore, K.C.B., was born in Edinburgh in 1816, and received his education at the high school and at the university of his native city. He first became known as an author by his contributions to "Fraser's Magazine" and "Tait's Magazine," under the signature of "Bon Gaultier," and in conjunction with the late Professor Aytoun he composed the *Book of Ballads*, which bears that pseudonym, and a volume of translations of the *Poems and Ballads of Goethe* (1858). His metrical translation of the *Odes of Horace* appeared in 1860, and was immediately republished in the United States. In 1882 Sir T. Martin completed his Horatian labors by a translation of Horace's whole works, with a life and notes, in two volumes. He has written several biographies, notably that of the Prince Consort.

MARTINEAU, James, an English theologian, brother of Harriet, born at Norwich, April 21, 1805. He was educated at the grammar school of his native city, and was appointed professor of mental and moral philosophy at Manchester New College. He removed to London when that institution was transferred thither in 1857. He became principal of the college in 1868, and held the office until his retirement in 1885. Martineau was recognized for fifty years as one of the profoundest thinkers and most effective writers of his day. He received the degree of LL.D. from Harvard in 1872; doctor in theology from Leyden in 1875, and that of D.D. from Edinburgh in 1884.

MARTINEZ CAMPOS, Arsenio, a Spanish general and statesman, born in 1834, left the staff school at Madrid with the rank of lieutenant, went through the campaign in Morocco in 1859, as a member of the staff of the commander in chief, O'Donnell, and was there promoted to the rank of major. In 1864 he joined the army of Cuba as colonel, and remained six years in that island. On his return to Spain in 1870 he was sent to join the army of the North, which was engaged in repelling the Carlist rebellion. After the abdication of King Amadeo he declined to give in his adhesion to the new order of things, and made no secret of his antipathy to the republic. He was put on the retired list in 1873, and shortly afterward was confined in a fortress as a conspirator. He was sent to the army of the North in April, 1874, to command a division of the third corps; took part in the engagements of La Munecas and Galdames, which led to the siege of Bilbao being raised, and was the first to enter the liberated city on May 1, 1874. When General Concha reorganized the Liberal army, Martinez Campos was appointed general in command of the 3d corps. General Martinez Campos, besieged at Zurugay by the main body of the Carlists opened a passage through the enemy's ranks at the head of a column which numbered barely 1,800 men, and went to rejoin at Murillo the headquarters, where he was able to organize the retreat of the army on Tafalla. Returning to Madrid, he continued to conspire almost overtly in favor of Don Alfonso, while Marshal Serrano, chief of the executive power, was operating against the Carlists. In conjunction with General Jovellar he made the military *pronunciamiento* of Sagonto, which gave the throne of Spain to Alfonso XII. The new government sent him into Catalonia as captain-general and commander-in-chief of that military district. In less than a month he pacified the country, put down the Carlist bands, and took the command of the army of the North. He brought the civil war to a close by the defeat of Don Carlos at Pena de Plata, in March, 1876. The high dignity of captain-general of the army, which is equivalent to a marshal of France, was the recompense for his signal services. A year afterward he was appointed commander-in-chief of the army in Cuba, which the rebels had held in check for seven years. On his return to Spain, General Martinez Campos accepted the portfolio of war and the presidency of the council (March 7, 1879), and endeavored to procure the fulfillment of the promises made to the Cubans; but not obtaining the support of the Cortes, he resigned, and was succeeded by Señor Cánovas del Castillo (Dec. 9, 1879). Early in 1881 the Conservative government of Señor Cánovas del Castillo was overthrown and a coalition between Señor Sagasta and General Martinez Campos came into power, and retained it till October, 1883, when it resigned in consequence of being unable to obtain from the French Government a satisfactory apology for the insult offered to King Alfonso by the Paris mob on his visit to Paris.

MARTINSBURG, the capital of Berkeley county, W. Va., is situated on Tuscarora Creek, in the Shenandoah Valley, 80 miles west of Washington. It contains a National and two other banks, carriage factories, foundries, distilleries, and machine-shops, has three newspapers, railroad and telegraph facilities, and a population of 7,200.

MARTIN'S FERRY, a village of Belmont county, Ohio. It contains important glass-works, said to be the largest in the United States, and has manufactures of engines and agricultural implements, and foundries. Pop. (1890), 6,250.

MARTINSVILLE, a post-village, the county-seat of Morgan county, Ind., 31 miles southwest of Indianapolis on White River. It has a large grain trade and contains a foundry, a machine-shop, a woolen factory, a flour-mill, and saw-mills. Pop., 2,680.

MARX, Karl, born at Treves, Germany, in 1818; was educated at Bonn and Berlin, and in 1843 became connected with a newspaper at Cologne. He was expelled successively from that city, from France and from Belgium, but returned to Germany during the revolutionary movement of 1848–49. Again banished, he sought refuge in London,

where he founded the "International," a federation of socialistic societies which undertook to reform everything. Marx wrote extensively on political economy, quarreled with his co-workers and established several newspapers for the dissemination of his own views, and died March 16, 1883. Marx, more than any other man, has influenced the labor movement all over the civilized world; his theories have in many ways penetrated the different strata of society, even the highest, but most of all the working-classes.

MARYLAND, STATE OF. For general article on the STATE OF MARYLAND, see Britannica, Vol. XV, pp. 602–605. The census of 1890 reported the area and population as follows: Total area of the State (including 2,350 square miles of water surface), 12,210 square miles. Population, 1,042,390, a gain during the decade of 107,447, or 11.49 per cent. Capital, Annapolis, with a population of 7,604.

The State is divided into twenty-three counties and the corporation of Baltimore city.

The total debt of the State on Oct. 1, 1891, was $10,721,642.52, and after deducting productive investments and cash on hand, the net debt was $3,876,046.88. The assessed value of property for the State levy in 1890 was $510,003,077, and the tax levy was 17¾ cents on each $100.

The total revenue received into the treasury during the fiscal year 1891 was $2,827,568.29 and the balance in the treasury Sept. 30, 1890, was $666,845.94, making a total amount in the treasury during the fiscal year $3,033,036.65.

The total disbursements during the fiscal year 1891 were $2,953,083.93, and the balance in the treasury at the end of the fiscal year was $541,330.30.

Maryland has an excellent system of public education. In 1891 the number of schools was 2,236, with an enrollment of 189,214 pupils out of a total number of 295,215, and an average daily attendance of 106,170. The receipts for school purposes from all sources were, in 1891, $1,987,109.44 and the total expenses were $2,302,270.49.

The imports from the port of Baltimore for 1891 amounted to $18,127,664, while the value of the exports, consisting largely of corn and wheat, was $79,217,082.

Western Maryland has unsurpassed agricultural lands besides extensive deposits of coal and iron. The yield of corn for 1891 was 18,511,000 bushels, that of wheat 5,838,000. The total output of the Cumberland coal region was 4,537,954 tons, an increase of more than 100 per cent. since 1881. Another important source of income is the oyster industry. In 1891 the sales amounted to 2,259,410 bushels. In 1890 by an act of the legislature the State adopted the Australian ballot, which was favorably passed on by the supreme court.

The governors of the State of Maryland from the beginning, and their dates of official service, are:

LORDS PROPRIETARY.

MARYSVILLE, a city, a railroad center and the county-seat of Yuba county, Cal., situated at the confluence of Feather and Yuba rivers. It manufactures woolen goods, flour, and carriages. Population, 3,991.

MARYSVILLE, the county-seat of Marshall county, Kan., on the east bank of Big Blue River. By means of a dam across the river the water-power is utilized by several mills. Pop., 1,913.

MARYSVILLE, a city, the county-seat of Union county, Ohio, about 30 miles northwest of Columbus. Pop., 2,810.

MARYVILLE, a railroad center, a city, and the county-seat of Nodaway county, Mo., 45 miles north of St. Joseph. Stock-raising and farming are the chief industries. Pop., 4,037.

MARYVILLE, a manufacturing town, the county-seat of Blount county, Tenn., about 15 miles south of Knoxville. It is the seat of Maryville College and the Freedman's College. Pop., 1,686.

MASENIA, or MASENA, a walled town of Africa, capital of Baghirmi, 100 miles southeast of Lake Chad. It is fairly well constructed on very rough ground, has a brick palace for the sultan, and is a place of considerable trade, but is decaying on account of its extreme unhealthiness.

MASON, a city, the county-seat of Ingham county, Mich., 12 miles south of Lansing. It has several mills. Pop., 1,875.

MASON, a post-village of Mason county, W. Va., on the south bank of the Ohio river, opposite Pomeroy, Ohio. It is a coal mining and shipping point,

manufactures nails and obtains salt from artesian wells. Pop., 1,029.

MASON, Charles (1730–1787), an American astronomer. For several years he was assistant at the Greenwich Observatory, and in 1763 was commissioner with Jeremiah Dixon to survey the boundary line between Pennsylvania and Maryland. In 1766 Mason and Dixon devoted some time, at the request of the Royal Astronomical Society, to determining the precise measure of a degree of latitude in America in the neighborhood of Pennsylvania, and in 1869 Mason observed the transit of Venus at Cavan, Ireland. He was subsequently employed by the Bureau of Longitudes to verify the lunar tables of Tobias Mayer.

MASON, David Hastings, born in Philadelphia, Pa., Jan. 8, 1828. For fifteen years he was engaged in newspaper work in Georgia and Tennessee. From 1867 to 1880 he was connected with the Chicago press, writing largely on the tariff and other economic questions. In 1871 he was the editor of a monthly magazine called "The Bureau," devoted to the promulgation of the theories of protection. In connection with Mr. J. J. Lalor he edited the *Cyclopædia of Political Science*, for which he wrote the article on protection. Mr. Mason has also written *A Short Tariff History of the United States* from 1783 to the present time. Only the first part bringing the history down to 1789 has appeared.

MASON, Edward Gay, born in Connecticut, Aug. 23, 1839. Graduated from Yale in 1860, he entered upon the practice of law in Chicago. In November, 1887, he was elected president of the Chicago Historical Society to succeed Elihu B. Washburne. Mr. Mason is prominent as a student of the early history of Illinois and has written pamphlets relating thereto. He has also made contributions to the magazines.

MASON, Francis, born in England, April 2, 1779. He acquired the rudiments of education from a retired naval officer. In 1818 he came to the United States. Marrying in 1825, under the influence of his wife, he united with the Baptist church, attended Newton Theological Seminary, and in 1830 sailed for Burmah as a missionary. He lived among the Karens at Tavoy for twenty-two years. In 1852 he became a member of the Royal Asiatic Society. The next year he removed to Toungoo, and the year following visited England and America. In 1860, when over sixty years of age, Dr. Mason learned the art of printing and produced the most creditable piece of book making ever put forth in Burmah. He died in Rangoon, Burmah, March 3, 1879. Dr. Mason was familiar with the Burmese, the Pali, and the Sanscrit languages; could speak the various dialects of India; and knew Syriac, Chinese, Chaldee, Arabic, and German. Two of the Karen dialects he reduced to written form, into which he translated parts of the scripture. In 1853 he published a translation into Karen of the whole Bible. He has published a Pali grammar and several other linguistic works of high value, which have become standard.

MASON, George (1725–1792), an American statesman. In 1776 he drafted the declaration of rights and the constitution of Virginia, which were unanimously adopted, and in 1787 was a member of the convention that framed the Constitution of the United States. He, however, was dissatisfied with the Constitution, and opposed its ratification. He was twice elected to the Continental Congress, but declined to serve; and was chosen the first United States Senator from Virginia, refusing also to act in this capacity. He then retired to his home on the Potomac, where he resided till his death.

MASON, James Murray, born in Fairfax county, Va., Nov. 3, 1798; died in April, 1871. He served many years in the Virginia house of delegates and sat in Congress as a Democrat from 1837 to 1839. From 1847 to 1861 he sat in the United States Senate from Virginia, but resigned to join the Confederacy. In the autumn of 1861 he was appointed with John Slidell as commissioner from the Confederate States to England. They sailed from Charleston, October 12th, for Cuba. Here they took passage for England on the British mail steamer *Trent*. This vessel was overhauled by a United States ship of war under the command of Commander Charles Wilkes, who demanded the bodies of Mason and Slidell, and the steamer being unarmed, the captain turned the men over to him. They were brought to Boston and confined in Fort Warren, and Congress passed a resolution of thanks to Wilkes for his prompt action. The British government made an immediate demand, and a peremptory one, for the delivery of the men whom they claimed were protected by the British flag. There was a great outcry against surrendering them, but Abraham Lincoln showed his good sense and political wisdom by giving them up. This occurrence, known as the *Trent* affair, intensified the ill-feeling between England and the United States, which had grown out of the expressions of sympathy made by the English aristocrats for the Confederates.

MASON, Jeremiah (1768–1848), a United States Senator. In 1791 he was admitted to the New Hampshire bar, and in 1802 became attorney-general of the State. From 1813 to 1817 he was a United States Senator, and then for several sessions was a member of the legislature. From 1829 to 1832 Mason was president of the Portsmouth, N. H., branch of the United States bank. He then settled in Boston and continued his practice of law until 70 years of age.

MASON, John, the founder of New Hampshire, died in 1635. In 1616 he was sent to Newfoundland from England as governor, and during the war with Spain from 1624 to 1629 was treasurer and paymaster of the English forces. He then procured a grant of territory on the coast between the Merrimack and Piscataqua rivers, which was designated as New Hampshire, and soon afterwards formed a colony there. Just before his death he was appointed vice-admiral of New England.

MASON, John (1600–1672), an American soldier. In 1635 he aided in founding the town of Windsor, Conn., and in 1637 commanded a successful expedition against the Pequod Indians, in which he annihilated, with a handful of whites, a powerful tribe, and secured a general peace with the Indians, which remained unbroken for forty years. Mason then settled in Saybrook and later in Norwich, and was major of the colonial forces more than thirty years. From 1642 to 1668 he was a magistrate, and from 1660 to 1670 the deputy governor of Connecticut.

MASON, John Mitchell (1770–1829), an American Calvinistic clergyman. In 1792 he became pastor of the Cedar street Associate Reformed Church, New York city, resigning in 1810 to form a new congregation. In 1811 he was chosen provost of Columbia College, and in 1821 president of Dickinson College, Pa. He resigned in 1824 on account of failing health, and was never again able to assume any official employment. Dr. Mason published a number of orations, addresses and sermons, and among other works *A Plea for Sacramental Communion on Catholic Principles* (1816).

MASON, John Young (1799–1859), a United States cabinet officer. In 1819 he began the practice of law in Southampton county Va., and was a

member of the legislature in 1829. From 1831 to 1837 he was a member of Congress, and later was judge of the United States district court and of the circuit court of Virginia. In 1844 he became Secretary of the Navy, and in 1845 was appointed United States attorney-general; but the following year was again placed at the head of the navy department. From 1853 till his death he was United States minister to France.

MASON, Sir Josiah, an English philanthropist, born at Kidderminster, Feb. 23, 1795, died at Erdington, June 16, 1881. He began life by selling cakes on the street, and after turning his hand to various employments took the split-ring business of Mr. Harrison at Birmingham. He began to make pens for Perry & Co., and his business increased till he became the largest penmaker in the world. Partner with Elkinton in his electro-plating trade, he gave Dr. C. W. Siemens his first start in life by paying him $8,000 for a patent; and he paid Krupp, founder of the works at Essen, $50,000 for the patent for machinery to roll the metal "blanks" from which spoons and forks are made. Mason erected and endowed almshouses, and an orphanage at Erdington, at a cost of $1,300,000, and was the founder of the Josiah Mason College at Birmingham.

MASON, Lowell (1792–1872), an American musician. At the age of sixteen he was so proficient in vocal music that he was leader of a Massachusetts village choir, and a teacher of singing-classes. From that time until his death he devoted his entire time to music, and probably did more to popularize vocal music than any other American. In 1855 he received from the University of the City of New York the degree of Mus. Doc. He has published several collections of hymns.

MASON, William E., was born in New York, July 7, 1850; removed with his parents to Bentonsport, Iowa, in 1858; taught school from 1866 to 1870, the last two years at Des Moines, Iowa; entered the law office of Hon. Thomas F. Withrow, and was admitted to practice law in Des Moines; went to Chicago in 1872, and has practiced law there ever since; was elected to the State house of representatives in 1879, to the State senate in 1881; was elected to the fiftieth Congress (1886), and was reëlected to the fifty-first Congress as a Republican, but was defeated in 1890.

MASON AND DIXON'S LINE, popularly supposed to have been a line dividing the slaveholding from the non-slaveholding States, and to have run due east and west. In reality it ran for more than one-third of its length between two slave States, Maryland and Delaware, and a small part of it is an arc of a circle. It was run by two English engineers, Charles Mason and Jeremiah Dixon, between the years 1764 and 1767, for the purpose of settling the disputed boundaries between Maryland on the one side and Pennsylvania and Delaware on the other. Their instructions were to begin at the most easterly point on the Atlantic Ocean, and run due west to a point midway between the Atlantic and the Chesapeake Bay; thence northward, so that the line should become a tangent to the northwestern boundary of Delaware, which was a circle described from New Castle Court-house as center, with a radius of twelve miles. The line was then to follow the curve in a westerly direction until it reached a point due north of the point of tangency; thence due north until it intersected a line run due west from a point fifteen miles south of Philadelphia; and thence due west until it intersected a line running due north from the most western source of the Potomac River. The work was done with such skill and accuracy that a revision in 1849, with instruments of much greater precision, disclosed no error of importance.

MASON CITY, a town of Mason county., Ill., situated in the best corn-growing region of the State. Pop. (1890), 1,869.

MASON CITY, an incorporated town, the county-seat of Cerro Gordo county, Ia. It has flour-mills, limestone quarries, good water-power, and is situated in a good agricultural region. Pop., 4,002.

MASONRY, the art of construction in stone. The earliest existing examples are among the most magnificent specimens of the art. No nation has excelled the ancient Egyptians, who did not use mortar in their important structures, such as the the pyramids, the joints being all carefully polished and fitted. Cyclopean masonry, of which remains exist in many parts of Greece and Italy, also exhibits stones of great size and with carefully-adjusted joints. The walls of Mycenæ are among the earliest examples. These are built with huge irregular blocks, the spaces between being filled up with smaller stones. The Etruscan specimens are more carefully executed; the stones are not squared, but they are all carefully fitted together. The masonry of the Greeks and Romans very closely resembled that of the present day: *Rubble-work* (*opus incertum*), in which the stones are not regularly coursed; *Coursed-work*, where the joints are all level and the stones of equal height; *Ashlar*, resembling the latter, but built with larger stones carefully dressed on the joints.

The early medieval masonry was of very bad construction, being, in fact, little better than common rubble, with an occasional use of Herring-bone work. The Normans improved upon this kind of work, but their masonry was also so bad that many of the towers built by them either fell or had to be taken down. The art gradually improved with the advance of Gothic architecture, and ashlar was reintroduced for all important works. The ashlar-work so constantly used in renaissance buildings has given place to the hammer-dressed and squared masonry. Special materials sometimes produce special kinds of work; thus, in Norfolk and Suffolk, where large flints abound, the walls are often faced with these, split so as so form a clean face and good joints, and arranged in bands or panels between stonework or brickwork.

MASPERO, Gaston Camille Charles, an Egyptologist, born at Paris, of Italian parents, June 23, 1846. He began to lecture on Egyptology at the school of higher studies in Paris, in 1869, and in 1873 was appointed professor of Egyptology at the College of France. In 1881 he founded a school of Egyptian archæology at Cairo, and succeeded Mariette as director of explorations and custodian of the Boulak Museum. In 1886 he became professor at the Institute of Paris. As an explorer he has excavated or opened the pyramids of the kings belonging to the 5th and 6th dynasties, and the burial-fields of Sakkara and Dashûr, and discovered new sepulchral sites of great value at Deir el-Bahari, near the entrance to the valley of the Tombs of the Kings, at Ekhmim, 130 miles south of Thebes, and at other places.

MASQUERADE, or Masked Ball, a festive meeting in which the host and guests assume fictitious characters, and disguise themselves more or less for the occasion, the name being derived from the use of the mask. The public mummeries of former times, Easter Plays, Festival of Fools, etc., which were frequent in Europe, probably suggested the idea of the masquerade. Catherine de Medici introduced the regular masquerade at the French Court. It found its way to England in the

reign of Henry VIII., but did not reach any of the courts of Germany till the end of the 17th century.

MASSACHUSETTS, STATE OF. For general article on the STATE OF MASSACHUSETTS, see Vol. XV, pp. 611–616. The census report of 1890 gave the revised figures as to the area and population of Massachusetts as follows: Total area, 8,315 square miles, including 275 square miles of water; population, 2,238,943, a net gain during the last decade of 455,858, or 25.56 per cent. Capital, Boston, with a population in 1890 of 448,477, a gain during the decade of 85,638 or 23.60 per cent.

The railroad system of Massachusetts is widely extended. The railroad commissioners in their report for the year ending June 30, 1891, gave the following figures: There were 52 corporations owning 3,216.966 miles of main line and branches, of which 1,121.977 miles were double-tracked, while the total length of sidings was 1,582.965 miles. The average cost of standard guage road was returned at $70,653.65 per mile, and the cost of equipment per mile operated, $7,103.48, making the average total cost of $77,750.13. The aggregate capital stock of the 52 corporations was $158,488,426.15, with net debt of $112,142,465.58. The gross earnings were $61,483,104.33, while the operating expenses were $42,432,062.76, making the net income $19,051,041.57. The average sum earned on each mile operated was $15,413.16. Of the 52 corporations reported, 34 declared dividends ranging from 2 to 10 per cent., amounting to $9,013,516.74. The whole number of employés was 42,289.

There were reported 56 street railway companies, operating 674.132 miles of road, with capital stock of $19,553,952.48 and gross earnings of $8,901,123.36. According to the report this included 279.439 miles of electric road using the "overhead" system, and 9.590 miles using the "storage-battery" system. There are under construction 11.100 miles of "overhead" system.

The State militia had an authorized strength of 417 commissioned officers and 5,776 enlisted men. The aggregate number on the rolls was 406 commissioned officers and 4,923 enlisted men. The number liable to military duty in the State was 357,713. The total military expense for the year was $235,660.82.

The report of the State auditor for the year ending Dec. 31, 1891, gave the following figures: Cash in the treasury Jan. 1, 1891, $1,488,057.19; cash received during the year, $18,792,998.53—total, $20,281,055.72. The expenditures, ordinary and exceptional, for the year were $18,956,569.52, while the actual expenses of government were $6,005,693.15. The balance in the treasury Jan. 1, 1892, was $1,324,486.20. The revenue arising from licenses, fees, the income of certain institutions, the taxation of property, and corporate franchises for the year 1892 was estimated at $5,301,082.58, and the expenses for the year at $6,357,529.38, leaving a deficit of $1,056,446,80. The State debt, Jan. 1, 1891, was $31,381,158.30, and Jan. 1, 1892, had been reduced to $27,929,415.55.

In 1891, 1,538 corporations made reports. The aggregate capital invested was $250,204,938, with total assets $477,074,407, and total liabilities $479,036,971. Herein were included 458 stock companies with capital stock of $15,757,415,incorporated in 1891.

The manufacturing interests of the State are large and include every variety of industry. Among the principal manufactures are food-preparations, furniture, machinery, paper and paper goods, wooden and woolen goods. The whole number of private firms and corporations reporting to the bureau of statistics at the close of the year 1891 was 4,865, with an output of $669,935,835. Of these 3,745 had reported in 1890 an output of $613,100,717. In the comparative report of the bureau of statistics, of 3,745 reported, 730 were corporations: the whole number of individuals interested as partners or stockholders was 40,334, and the total capital invested was $434,656,302. The aggregate number of employés was 292,866, of whom about one half was composed of women. The total paid for labor was $129,416,248, an average of $441.90 per capita.

The Savings Banks Commission, in its report for the year ending Dec. 31, 1891, gave the number of savings banks as 180, with assets of $390,565,967.10. The deposits amounted to $369,526,385.54, an increase of $15,933,488.40. The number of deposits, not including dividends, was 968,750, a decrease of 92,127. The average account was $326.67. The cost of management was $882,787.61. The commission further reported 19 trust companies with assets of $82,124,296.16 and 108 coöperative banks with assets of $11,874,530.14. The grand total of institutions reported was 312 with assets of $487,053,546.26, which gives an increase of eleven institutions with an increase of assets of $27,718,486.64. According to an act approved March 23, 1892, the total valuation of taxable property was placed at $2,429,832,966.

The chief agricultural products were reported by the United States commissioner of Agriculture as follows:

| Products. | Quantity produced. | No. of acres in each crop | Total valuation. |
|---|---|---|---|
| Indian corn.....bushels | 2,124,000 | 59,997 | $ 1,486,800 |
| Wheat..... " | 16,000 | 1,080 | 16,000 |
| Rye..... " | 245,000 | 23,550 | 181,300 |
| Oats..... " | 703,000 | 24,752 | 302,290 |
| Barley..... " | 75,000 | 3,313 | 54,750 |
| Buckwheat..... " | 77,000 | 5,387 | 52,360 |
| Potatoes..... " | 2,350,000 | 35,608 | 2,162,000 |
| Tobacco.....pounds | 3,511,000 | 2,464 | 596,904 |
| Hay..... tons | 770,702 | 642,252 | 12,177,092 |

The fisheries of the State are of great importance, the capital invested being $8,660,581 and the annual production $6,462,692. The fishing fleet comprised at the last State census 866 vessels and 5,549 dories and other boats. The total tonnage was returned as 68,211. Most of the fishing-vessels were built in the State and some in Maine.

Education receives the greatest attention in Massachusetts, the home of the public school. The last official census showed that the total number of children between 5 and 15 was 376,491; while 376,986, of all ages, attended the public schools. The average attendance of the pupils was 278,602. The number of teachers employed was 10,646, of whom 1,016 were men and 9,630 women. The average paid monthly to the men was $118.07, that to women $48.17. The number of schools in the State 7,239. There were 244 high schools with 26,294 students; 1,018 evening schools with 28,453 pupils and an average attendance of 14,526. The total amount raised for the school fund by taxation was $5,707,514.37, while the total expense was $8,554,545.51. The number of private schools and academies was 471, with 59,030 pupils. There were six normal schools with an attendance of 1,204, including 225 at the Normal Art School. Of institutions for higher education the most important is Harvard College at Cambridge. An extended notice of this college, as also of Williams, Amherst, Tufts, and other colleges, will be found under the head of UNIVERSITIES.

The State has a very large number of daily and weekly newspapers, and the publishing and printing interests are largely represented.

Libraries abound in Massachusetts. The Boston Public Library is treated of elsewhere (see LIBRARIES). According to a late report there were within the State 703 secular and 1,668 religious libraries, containing a grand total of 5,876,856 books and pamphlets. In 1891 the State Library added 3,107 volumes, 3,479 pamphlets and 85 maps to its collection at an expenditure of $5,908.67.

The report of the Board of Commissioners of Prisons for the year ending Sept. 30, 1892, showed the average number of prisoners in the State prison, the State reformatories, the county prisons and houses of correction to be 6,835, with an aggregate expenditure of $1,093,446.71, receipts from labor $201,367.79. Net cost, $892,078.92, average net cost $130.52. The State Board of Lunacy and Charity reported for the year ending Dec. 31, 1891: Whole number supported in almshouses, hospitals for the insane, schools for the feeble-minded and elsewhere to be 13,627, of which 3,578 were lunatics. The aggregate average was 8,526.4 with an average of lunatics 2,742.2. The whole number of persons partially supported was 45,235, including 19,334 children. The total expenditure for the year was $1,209,038 for full support in State establishments, $666,766 for partial support, and $188,023 for administration, making a total expenditure of $2,063,827, of which $189,330 was reimbursed, making net cost of support $1,874,497.

At the session of the State legislature in 1892 an act was approved to form a dairy bureau for the protection of farmers against imitations of butter. Provision was also made for a nautical training school with an appropriation of $50,000 for its maintenance on condition that the United States furnish a suitable vessel. Another important act was that incorporating the "Trustees of Public Reservations" to preserve and maintain historic sites within the limits of the State. The tax qualification for suffrage was abolished by an amendment submitted to the people in 1891.

MASSAGETÆ, a wild and warlike people, who inhabited the broad steppes on the north-east of the Caspian Sea, to the northward of the river Araxes or Jaxartes. Herodotus says that they had a community of wives; that they sacrificed and devoured their aged people; that they worshipped the sun and offered horses to him; that they lived on the milk and flesh of their herds, and on fish, and fought on horseback and on foot with lance, bow, and double-edged axe. Cyrus is said to have lost his life in fighting against them, 530 B. C.

MASSASOIT, Indian chief, born in Massachusetts, about 1580; died there in 1660. His control extended from Cape Cod to Narragansett Bay. In March, 1621, an Indian, whom the whites called Samoset, appeared three months after the founding of Plymouth, and called, in broken English, taught him by some fishermen, "Welcome, Englishmen." He said he came from the great sachem, Massasoit. After some parleying the chief appeared in person, was received with deference, and a treaty of amity was concluded with his tribe and their confederates, and honorably kept for fifty-four years—beyond the lifetime of Massasoit. When Roger Williams was banished from Massachusetts, and went on his way to Providence, he was entertained by Massasoit for several weeks. Massasoit lived and died a sincere friend to the white settlers. His sons were Alexander and "King" Philip.

MASSÉ, VICTOR, a French musical composer, was born March 7, 1822. He was educated at the Paris Conservatory and produced his first work for the stage in 1852. Among his compositions the best known are *Galatea*, *Paul and Virginia* and *The Seasons*. He died July 6, 1884.

MASSENET, JULES EMILE FREDÉRIC, a French composer, born at Montaud, May 12, 1842. He studied at the Paris Conservatoire, obtained the first prize for pianoforte in 1859, the first for fugue and the Prix de Rome for his cantata *David Rizzio* in 1863. He travelled through Italy and Germany, and made his *début* at the Opera Comique, Paris, in 1868, with "La Grand-Tante." In 1878 he was appointed Professor of Composition at the Conservatoire, and elected a member of the Académie des Beaux-Arts. He is the author of *Esclarmonde*, a romantic opera which had a run of 100 representations without interruption, 1889; and a large number of melodies, pieces for the pianoforte and a series of seven *Suites d'Orchestre*. He has written also some entr'acts and stage music for Sardou's dramas *Theodora* and the *Crocodile*.

MASSEY, GERALD, was born of very poor parents at Tring, Hertfordshire, May 29, 1828, and received a scanty education at the British and National Schools. At eight years of age he was working twelve hours a day in a silk manufactory. At the age of fifteen he went to London and found work as an errand boy, and at twenty-one he became editor of the "Spirit of Freedom." The following year he was one of the secretaries of the "Christian Socialists," and a personal friend of Charles Kingsley and F. D. Maurice. In 1854 he published *The Ballad of Babe Christabel and Other Poems*, which entered its fifth edition at the end of the year. He then joined the staff of the Athenæum, and for ten years wrote a considerable number of its reviews. For several years he wrote on literary subjects in the "Quarterly Review." As early as 1852 Mr. Massey began to take a great interest in mesmerism, spiritualism, and kindred subjects, and he has since delivered many lectures on such matters, both in London and abroad. He has lectured all through North America, Australia, and the colonies, twice from New York to San Francisco, where he is better known and more highly thought of than in England. Of late years he has written very little poetry, but has recently published his *Collected Poems*, in 2 vols., under the title of *My Lyrical Life*. He has also re-written his work on the *Secret Drama of Shakespeare's Sonnets*. He has written several other works and has contributed to English and American periodical literature.

MASSILLON, a city of Ohio, on four lines of railway and on the Ohio canal. Pop. in 1890, 10,092. See Britannica, Vol. XV, p. 617.

MASSON, DAVID, Professor of Rhetoric and English literature in the University of Edinburgh, was born Dec. 2, 1822, in Aberdeen, and educated at Marischal College in that city, and at the University of Edinburgh. He began his literary career at the age of nineteen, as editor of a Scotch provincial newspaper, and repairing, in 1844, to London, where he remained about a year, contributed to "Fraser's Magazine" and other periodicals. He established himself in Edinburgh for two or three years, as a writer for periodical publications, besides having special engagements with the Messrs. Chambers, but returned to London in 1847, where he resided for eighteen years, and was appointed to the chair of English Language and Literature at University College, London, on the resignation of the late Professor Clough in 1852. He retired from his post in Oct., 1865, having been appointed Professor of Rhetoric and English Literature in the University of Edinburgh. He contributed numerous articles to the Quarterly, National, British Quarterly, and North British Reviews, to the "Encyclopædia Britannica" and the "English Cyclopædia," and in 1859 became editor of "Macmillan's Magazine," which he conducted for a good many years, and to

which he has largely contributed. Mr. Masson has written very important works in literary and philosophical criticism and several literary biographies. His great work is his ponderous *Life of John Milton, narrated in connection with the Political, Ecclesiastical and Literary History of his time* (6 vols. 1859–80), the most complete biography of any Englishman, and of great value for contemporary history. He was Rhind lecturer in 1885, and after 1879 he edited the *Register* of the Privy-council of Scotland, contributing the introductions to it.

MASSORAH, or MASORA "tradition," a collection of critical notes on the text of the Old Testament, its divisions, accents, vowels, grammatical forms, and letters (see HEBREW LANGUAGE, Britannica). There can hardly be a doubt that the Massorah, like the Halacha and Haggada, was the work, not of one age or century, but of many ages and centuries, as, indeed, we find in ancient authorities mention made of different systems of accentuation used in Tiberias, Babylon (Assyria), and Palestine. It was in Tiberias also that the Massorah was first committed to writing between the 6th and 9th centuries A.D. Monographs, memorial verses and glosses on the margins of the text seem to have been the earliest forms of the written Massorah, which gradually expanded into one of the most elaborate and minute systems, laid down in the "Great Massorah" (about the 11th century), whence an extract was made known under the name of the "Small Massorah." The final arrangement of the Massorah, which was first printed in Bomberg's Rabbinical Bible (Venice, 1525), is due to Jacobben-Chayim, of Tunis, and to Felix Pratensis. The language of the Massoretic writers is Chaldee, and the obscure abbreviations, contractions, symbolical signs, etc., with which the work abounds, render its study exceedingly hard. Nor are all its dicta of the same sterling value; they are not only sometimes utterly superfluous, but downright erroneous. See Dr. Ginsburg's great work on the Massorah.

MASTERS, MAXWELL TYLDEN, M.D., F.R.S., born in 1833, at Canterbury, was educated at King's College, London, after which he practiced medicine for some years. He held the lectureship on botany at St. George's Hospital from 1855 to 1868, and became principal editor of the "Gardeners' Chronicle" in 1865. Doctor Masters has been botanical examiner in the University of London; is a fellow of the Royal Linnean, and Royal Horticultural Societies; an associate of King's College; an honorary or corresponding member of the principal horticultural societies of Belgium, France, Germany, Russia, Italy, and America, and of the Royal Society of Sciences of Liége, the Society of Natural Sciences of Cherbourg, the Botanical Society of France, and correspondent of the Academy of Natural Sciences of Philadelphia.

MASUDI, ABUL HASSAN ALI, an Arab traveller and author (died 957), was born at Bagdad about the end of the 9th century, and spent great part of his life in travel, visiting Egypt, Palestine, the Caspian shores, India, Ceylon, Madagascar, and perhaps even China. His chief works are the *Annals*, of which an abridgment, *The Meadows of Gold*, was printed with a French translation by Meynard in 1861–77 (one vol. of an English translation by Springer in 1841), and the *Indicator*.

MATE, is an assistant, a deputy, or a second in any work. In the navy the use of the term is now confined to petty officers, such as boatswain's mate, gunner's-mate, etc. In the merchant-service the mates are important officers, holding functions not greatly inferior to those of lieutenants in the royal navy. The first mate ranks next to the master or captain, commands in his absence, and is immediately responsible for the state of the vessel.

MATHEMATICIANS (Lat. *mathematici*), the name given by the Romans to the professors of astrology, from the fact that those who practiced astrology to some extent cultivated mathematical science. The Romans, unlike the Greeks, appeared not to comprehend the attractions of mathematical studies, and, being unable to distinguish between the student of pure science and the fanatic enthusiast who attempted to derive knowledge of future events on this earth from the position of the stars, joined them together in a common condemnation under the name of "mathematici."

MATHER, INCREASE, a famous American colonial divine, was the sixth son of Richard Mather, an English Nonconformist minister, who emigrated to Massachusetts in 1635. He was born at Dorchester, Mass., June 21, 1639, graduated at Harvard College in 1656, and again at Trinity College, Dublin, in 1658. His first charge, at Great Torrington in Devonshire, was given him on the advice of John Howe. He next preached in Guernsey, but in 1661, finding it impossible to conform, returned to America, and in 1664 was ordained as pastor of the North Church, Boston, where he remained till his death, Aug. 23, 1723. In 1681 he was also chosen president of Harvard College. An industrious student, he published no less than 136 separate works, most of which are now very scarce. Of these the most interesting, *Remarkable Providences* (1684), was reprinted in London, in 1856. *The History of the War with the Indians* (1676) was reprinted at Boston, in 1862. Mather's influence was great in the colony, and in 1689 he was sent to England to lay its grievances before the king. He was successful in obtaining a new charter from William III., and on his return was thanked by the speaker of the general assembly. The same year he became the first D.D. of Harvard. To his credit he was far less an alarmist about witchcraft than his son, and he had the good fortune to be absent in England during the time of fiercest excitement in the Salem mania. His *Causes of Conscience Concerning Witchcraft* (1693) did much to cool the heated imaginations of the New England colonists, and saved lives by refuting the doctrine of "spectral evidence."

MATHER, RICHARD HENRY, born in Binghamton, N. Y., Feb. 12, 1835, graduated at Amherst, 1857, and taught Greek and German in that university for many years. He became D.D. in 1879, and is the well-known author of several Greek text-books.

MATHERS, HELEN BUCKINGHAM (MRS. HENRY REEVES), novelist, was born in 1852 at Somerset, England. Her first novel was *Comin' Thro' the Rye* (1875), which immediately secured popularity, and was rapidly translated into more languages than any of Dickens' works. *The Token of the Silver Lily*, a poem, was published in 1876, and soon sold out; *Cherry Ripe*, Miss Mather's second novel, was published in 1877, and followed in 1878 by *The Land o' the Leal*, and *As He Comes up the Stair*, which are novelettes. Her third novel, *My Lady Green Sleeves*, appeared in 1879, and was followed in 1881 by *The Story of a Sin*. *Sam's Sweetheart* and *Eyre's Acquittal* were published in 1883 and 1884, and *Found Out*, which appeared in 1885, were rapidly followed by that series of cheap novels by many authors which has since become so popular.

MATHEWS, CHARLES JAMES, actor, born in London, England, in December, 1803; died in England, June, 1878. He made his first appearance on the stage in 1835, and for more than forty years was the leading exponent of light comedy on the English stage. Mathews visited this country twice and was well received.

MATHEWS, William, born in Waterville, Me., July 28, 1818; practiced law in Washington, and published newspapers in Maine and in Boston, and in 1856 removed to Chicago. He became professor of rhetoric and English literature in the University of Chicago in 1862. He retained that position for thirteen years, and in 1880 he removed to Boston, where he is still residing. He is the author of many works of general circulation.

MATHILDE, Princess (Mathilde Lætitia Wilhelmine Bonaparte), daughter of the ex-King Jerome and Princess Catherine of Würtemberg, and cousin of Napoleon III., was born at Trieste, May 27, 1820, and married at Florence, Oct. 10, 1841, to the Russian Prince Anatole Demidoff. This union was not happy, and in 1845 they separated by mutual consent, her husband being compelled by the czar to allow the princess an annuity of 200,000 roubles. From 1849 till the marriage of Napoleon III. she did the honors at the palace of the president, and on the reëstablishment of the empire was comprised among the members of the imperial family of France, and received the title of highness.

MATSUMAI, a seaport of Japan, situated at the southwest extremity of the Island of Yesso, at the western entrance of the Strait of Tsugaru. Formerly the principal town of the island, it has in recent times been outstripped by Hakodate. Population in 1887, 31,037.

MATTEAWAN, a post-village of Dutchess county, N. Y., on Fishkill Creek, 1½ miles above Fishkill Landing. Here felt goods, hats, lawn-mowers, wood-working machinery and files are manufactured. Pop., 4,278.

MATTHEWS, Brander, born in New Orleans, Feb. 21, 1852, graduated at Columbia in 1873 and was admitted to the bar. He has written several successful plays and many essays upon lives of actors and authors. He is professor of English literature at Columbia College, New York.

MATTHEWS, Henry, Q.C., M.P., was born in 1826, in Ceylon, where his father was a judge. After graduating at the universities of Paris and London he was called to the bar at Lincoln's Inn. He has been engaged in several of the great cases of his time, notably the Home case, the Tichborne case, and the Crawford case. He contested the borough of Dungarven three times unsuccessfully, but sat for it from 1868 to 1874. At the general election of 1886 he was returned for East Birmingham, being the first Conservative who ever sat for Birmingham. On the formation of Lord Salisbury's second ministry, Mr. Matthews was appointed home secretary, which position he held until 1892.

MATTHEWS, Stanley, born in Cincinnati, July 21, 1824; died, March 22, 1889. He graduated at Kenyon College in 1840, and practiced law for a short time in Tennessee. He removed to Cincinnati and became connected with the "Herald" of that city, an ardent anti-slavery paper, which he conducted for several years. He was elected judge of the court of Hanover county, afterward became State senator, and from 1858 to 1861 United States attorney for the southern district of Ohio. He entered the volunteer service in March, 1861, and served in western Virginia and with the army of the Cumberland. He resigned in 1863 to become judge of the superior court of Cincinnati, and was an unsuccessful candidate for Congress in 1876. In 1877 he was counsel for the Republicans in the Florida and Oregon cases before the Electoral Commission. In March, 1877, he was elected United States Senator and took the place of John Sherman, who had resigned. In 1881 Mr. Matthews was appointed, by President Garfield, associate justice of the United States Supreme Court.

MATTERHORN, called by the French Mont Cervin, and by the Italians Mont Silvio, a peak of the Alps between the Swiss canton of Valais and Piedmont, rises to the altitude of 14,705 feet. The actual peak was first scaled by Lord Francis Douglas, the Rev. C. Hudson Hadow, and Whymper, with three guides, July 14, 1865, when the three first-named and one of the guides fell over a precipice and were killed.

MATTO GROSSO ("dense forest"), an inland state of Brazil, bordering on Bolivia. Within this vast territory several great rivers rise, including the Madeira and Paragua. The vegetation is generally scanty, high trees and rich vegetation being confined to the river valleys. The gold and diamonds of Matto Grosso have been exhausted, and agriculture (insufficient for the wants of the state) and cattle raising are the principal industries. The former capital, Matto Grosso, decayed with the gold-mining industry, and is now a fever haunted place with 1500 inhabitants. See Britannica, Vol. IV, pp. 234, 235.

MATTOON, a post-town of Illinois, is an important railroad center. It lies in Coles county, and has considerable manufactures. It has banking, school, and church accommodations, and several newspapers are published here. It has telegraph facilities, and the car-shops of the Illinois Central Railroad are located here. Pop., 6,833 (1890 census).

MAUCH CHUNK, a mining town, the county-seat of Carbon county, Pa., situated among picturesque hills on the Lehigh River, ninety miles by rail north-northwest of Philadelphia. There is a switchback railway, nine miles long, from the town to Summit Hill—a place famous for its "burning mines," which have been on fire since 1858. Pop. in 1890, 4,101.

MAUCHLINE, a town of Ayrshire, 13 miles east-northeast of Ayr, and 10 south-southeast of Kilmarnock. It has long been noted for its wooden snuff-boxes and similar nicknacks. There is a monument (1830) to five martyred covenanters; and one mile north is Mossgiel, Burns's farm from 1784 till 1788; while in the village itself are "Poosie Nancy's," the scene of his *Jolly Beggars*, and Mauchline kirk, of his *Holy Fair*. Pop., 1,616.

MAUDSLEY, Henry, M.D., was born Feb. 5, 1835, and educated at University College, London. He studied medicine at University College, and graduated M.D. at the University of London in 1857. Doctor Maudsley was physician to the Manchester Royal Lunatic Hospital, 1859–62; was made fellow of the Royal College of Physicians in 1869; and was appointed Gulstonian lecturer to the college in 1870. He is a fellow of University College, London; was lately professor of medical jurisprudence in University College, and is consulting physician to the West London Hospital; and an honorary member of various learned societies in Paris, Vienna, Italy, and America. He has written several books on mental physiology and diseases.

MAUPASSANT, Guy de, a clever French writer, was born Aug. 5, 1850, at the castle of Miromesnil in Normandy, and, after carrying a musket through the Franco-German war, was initiated by Gustave Flaubert into the craft of letters. He attached himself to the younger branch of the naturalistic school, and wrote himself in by a story contributed to the "Soirées de Médan" (1880). He next produced a play, *Histoire du Vieux Temps*, and a striking volume of lyrics published under the title *Des Vers* (1880). But he won his real reputation as a novelist and storyteller.

MAUREPAS, Jean Frédéric Phélypeaux (1701-1781), a French statesman. When 14 years of age he was appointed minister of marine, and in 1738

became minister of state. In 1774 he was made minister of the council.

MAURER, Konrad von, a German archæologist, born at Frankenthal, in Rhenish Bavaria, in 1823. After being educated at Munich, Leipzig and Berlin, he was in 1847 made professor of jurisprudence at Heidelberg. He has devoted a great deal of time and study to the early Scandinavian history, laws, language, and literature.

MAURITIUS (see Britannica, Vol. XV, pp. 639–42). The government of the British Colony of Mauritius, with its dependencies, Rodrigues, Diego, Garcia, and the Seychelles Islands, is vested in a governor, aided by an executive council, of which the officer in command of her majesty's troops, the colonial-secretary, the procureur-general, the receiver-general, and the auditor-general, and two elected members of the council of government are ex-officio members. There is also a council of government, consisting of the governor and twenty-seven members, ten being elected, eight ex-officio, and nine nominated by the governor. The official councillors comprise the five executive members, the collector of customs, the protector of immigrants, and the surveyor-general. The constitution was altered by letters-patent dated Sept. 16, 1885, which introduced an elective element into the legislature. Mauritius comprises an area of 705 square miles, and on Jan. 1, 1891, had a population of 377,986, of whom 258,985 were Indian and 4,084 were Chinese. The revenue of the colony in 1890 was $2,487,926.68, with an expenditure of $2,465,699.52. The whole debenture debt of the colony at last report was $3,905,745. The declared value of the exports of the colony for the year 1890 was $8,628,137.60, while the imports amounted to $5,240,120.64. The staple export is unrefined sugar, while other exports are vanilla, aloe-fiber, cocoanut oil, rum, hemp-fiber, and caoutchouc.

The colony has two lines of railway of a total length of 92 miles, with a large revenue. There is a complete system of telegraph throughout the island. The post-office, according to the last annual report, handled 2,312,086 pieces of mail. All accounts are kept in rupees, and since May 1, 1878, the metric system has been in force.

MAUSOLEUM, a sepulchral monument of large size, containing a chamber in which urns or coffins are deposited. The name is derived from the tomb erected at Halicarnassus to Mausolus, king of Caria, by his widow, Artemisia, in 353 B. C. (See Halicarnassus, Britannica, Vol. XI, pp. 383, 384.) It was esteemed one of the seven wonders of the world. Although apparently in good condition as late as the 12th century, it fell into decay during the following two centuries. The ruins were ransacked for building materials by the Knights of St. John in the 16th century. The site was re-discovered in 1857 by Newton, who was instrumental in getting the remains carried to the British Museum. The mausoleum consisted of a basement 65 feet high, on which stood an Ionic colonnade 23½ feet high, surmounted by a pyramid, rising in steps to a similar height, and on the apex of that stood a colossal group, about 14 feet in height, of Mausolus and his wife in the *quadriga;* these statues are supposed to have been the work of the celebrated Scopas. Later instances, of large and magnificent mausoleums are Metella's tomb, Hadrian's (Castle of San Angelo) and that of Augustus at Rome, the mausoleum of Frederick William III. and Queen Louisa at Charlottenburg near Berlin, that of the House of Hanover at Herrenhausen, of the Prince Consort at Frogmore in Windsor Park, of Napoleon III. at Farnborough.

MAUSTON, the county-seat of Juneau county, Wis., 124 miles west of Milwaukee. It has excellent schools, good water-power, and manufactures lumber, barrels and carriages. Pop., 1,343.

MAVROCORDATOS, Alexander, a Greek statesman, born at Constantinople in 1791, died at Ægina in 1865. He took a prominent part in the struggle for the independence of Greece, presided in the first national assembly, and was afterwards distinguished as a general. When Otho was made king of Greece he was several times prime minister, and also ambassador to Prussia, England and France, holding the latter post 1850–54.

MAX-MÜLLER, Friedrich, philologist, born at Dessau, Dec. 6, 1823. His father, Wilhelm Müller, was librarian of the ducal library, but died prematurely in 1827. Max-Müller received the elements of his education at Dessau, and then went to Leipzig, where he studied Greek and Latin and took his degree in 1843. He began the study of Sanskrit and chose it as his special pursuit. The first fruits of his labors appeared in a translation of the *Hito padesa.* In 1844 he went to Berlin to study and to consult the Sanskrit MSS. to be found there. In Paris, whither he repaired in 1845, he began to prepare for an edition of the Rig-Veda, with the commentary of Sâyanâcârya. With this view he went to England in 1846, to examine the MSS. in the East India House, London, and the Bodleian Library at Oxford. The East India Company commissioned him to edit the Rig-Veda at its expense. In 1850 Max-Müller was appointed professor of modern languages at Oxford; and in 1858 he was elected a fellow of All Souls. While pursuing his labors connected with the Rig-Veda, Max-Müller has published treatises on a variety of philological topics, which have done more than the labors of any other single scholar to awaken a taste for the science of language in its modern sense. He has at command such a felicity of illustration that subjects dry under ordinary treatment become in his hands attractive. He is one of the eight foreign members of the Institute of France, and one of the twenty knights of the Ordre pour le Mérite. He has received the degree of LL.D. from Cambridge, Edinburg and Bologna.

MAY, Thomas, dramatist and historiographer, was born in 1594. Educated at Cambridge, he became a member of Gray's Inn and a courtier. He produced several dramas and comedies, poems, and translations of the Georgics and Lucan's *Pharsalia.* During the civil war he was made secretary and historiographer to the Parliament, and in that capacity produced a *History of the Parliament of England, 1640–1643.* He died Nov. 13, 1650.

MAY, Sir Thomas Erskine (1815–1866), assistant-librarian of the House of Commons in 1831, and clerk of the House in 1871. He was called to the bar in 1838, was made in 1860 Companion, and in 1866 Knight Commander of the Bath, and shortly after his retirement from office in 1866 was raised to the peerage as Baron Farnborough, but died May 18 of that year. He has written *Constitutional History of England since the Accession of George III., 1760–1860,* a continuation of Hallam's work, of which French and German translations have appeared; and *Democracy in Europe: a History* (2 vols. 1877), a work characterized by great learning.

MAYER, Alfred Marshall, an American physicist, born in 1836. In 1856 he was made professor of physics and chemistry in the University of Maryland, and from 1859 to 1861 held a similar position in Westminster College, Mo. He afterwards held professorships in Pennsylvania College, and Lehigh University, until 1871, when he accepted the professorship of physics in the Stevens Institute of Technology, Hoboken, N. J.

MAYER, Brantz (1809–1879), an American author. He was admitted to the Maryland bar in 1829, and in 1843 was appointed secretary of legation to Mexico, In 1863 he became a paymaster in the United States Army, and served until 1871, when he retired with the rank of colonel.

MAYER, Constant, born in France, October 4, 1832; studied at the school of Fine Arts in Paris, and in 1857 removed to New York. He is best known by his genre pictures, many of which have been engraved. He is an associate of the National Academy, and member of the American Art Union. Among his works are portraits of General Grant and General Sherman.

MAYFIELD, a city, the county-seat of Graves county, Ky., on Mayfield Creek, twenty-six miles south of Paducah. It has tobacco-houses and manufactures flour and woolen goods. Pop., 2,909.

MAYHEW, Augustus (1826–1875), an English author, wrote in conjunction with his brother Henry ("the Brothers Mayhew") several notable works of humorous fiction. In addition he wrote several stories which were popular at the time.

MAYHEW, Henry, an English journalist and *litterateur*, born in London in 1812. He ran away from Westminster School, was sent on a voyage to Calcutta, and on returning was articled to his father, a solicitor. Mayhew's first adventure in literature was the starting, in conjunction with Gilbert à Beckett, of "The Cerberus," the production of which was stopped by à Beckett's father. The two youths in disgust left their homes, and with but fifteen shillings between them walked to Edinburgh, hoping to make fortunes there as actors and authors at the theater of which Mayhew's brother Edward was lessee; this failed, for they were at once sent back. In 1831 they started "Figaro in London," and the year following "The Thief." In 1841 Mayhew produced *The Wandering Minstrel*, a farce, and shortly after joined with his brother Augustus in one of the most successful of literary partnerships, during which (as "the Brothers Mayhew") they produced some remarkably clever works of fiction. One of the originators and first editor of "Punch," Mayhew was from early in the forties a voluminous writer on many subjects. His brother Horace (1816–72) also made some mark in literature, more especially of the humorous and ephemeral kind. He was a constant contributor to "Punch," of which he was at one time sub-editor. He died in 1887.

MAYNARD, Horace, born in Massachusetts, Aug. 13, 1814; died in Tennessee, May, 1882. He graduated at Amherst in 1838 and became instructor in the East Tennessee College. He was admitted to the bar of Tennessee and practiced until 1857, when he was elected to Congress on the Know-Nothing ticket. In 1864 he became attorney general of the State, and from 1866 to 1875 he served in Congress as a representative. From 1875 to 1880 he was United States minister to Turkey, and in August, 1880, became Postmaster General under Hayes, and served until March 4, 1881.

MAYOR, the chief magistrate of a city or corporate town. The mayor is the head of the local judicature, and the executive officer of the municipality. In England he is elected by the council from the aldermen or councilors, and holds office for a year only. The first mayor of London was appointed in 1189, the first mayor of Dublin in 1409. The mayors of London, York, and Dublin are called "Lord Mayor." The lord mayor of London is the representative of royalty in the civil government of the city. To sustain the hospitality of the city he receives an allowance of £8,000 a year, with the use of the Mansion House, furniture, carriages, etc. He is chosen by the Livery on the 29th of September, being commonly the senior alderman who has not already "passed the chair." Although the office is still one of dignity, it is only in the eyes of foreigners that the lord mayor of London is one of the most important public functionaries of the realm. The title of mayor is used to denote the chief officer of a city in the United States and the British colonies. In France the maire is first officer of a town, commune, or district.

MAYOR, The Rev. John Eyton Bickersteth, born in Ceylon, Jan. 25, 1825, and educated at Cambridge. He was appointed professor of Latin in the University of Cambridge in 1872, a position which he still holds. Professor Mayor has been very prominent in classical research, being at one time one of the editors of the "Journal of Classical and Sacred Philology" and of the "Journal of Philology." He is the author of several important works.

MAYSVILLE, a city of Kentucky, the river port of a rich territory. It contains some flour and lumber mills, distilleries, car-shops, etc. Pop. (1890), 5,358. See Britannica, Vol. XV, p. 651.

MAZARRON or Almazarron, a seaport town of Spain, twenty-seven miles from Cartagena. Pop., 11,002.

MAZURKA, a lively Polish dance, the music of which is three-four time with a strong accent on the second beat. It is danced by four or eight couples, and is much practiced in the south of Germany and in Poland, from whose province, Mazovia, it gets its name.

MAZZARINO, a town of Sicily, fifteen miles southeast of Caltanisetta. Pop., 12,964.

MEAD, Edwin Doak, was born in Connecticut in 1849; studied at Cambridge and Leipzig. As a lecturer Mr. Mead has made a specialty of philosophy and of American politics, history, and literature. He is editor of the "New England Magazine" and has written several critical studies in history and biography.

MEAD, Larkin Goldsmith, an American sculptor, born in 1835. He displayed talent for modeling at an early age, and in 1855 produced the *Recording Angel*. After completing several other works he went to Florence, Italy, where he has since resided. He has modeled numerous statuettes and many important groups.

MEADE, George Gordon, general in the United States army, was born in Cadiz, Spain, where his father was an agent of the United States navy, Dec. 30, 1815. He graduated at West Point in 1835, and, after serving but one year in the army, resigned to begin practice as a civil engineer. He was frequently employed by the Government, and reëntered its military service in 1842. He served with distinction on the staffs of Taylor and Scott in the Mexican war, and in scientific work. At the outbreak of the civil war he was placed in command of a brigade of volunteers, soon rising to the command of a division, and joining his fortunes permanently to those of the Army of the Potomac. He led his division through the Seven Days' battle, being severely wounded at Glendale, through the Antietam campaign, and at Fredericksburg, where he particularly distinguished himself. At Chancellorsville he commanded the Fifth Corps; and when Hooker resigned the command of the army, and while the army itself was in hasty movement northward to check Lee's invasion of the North, in 1863, Meade was appointed to the command. He accepted it with the greatest reluctance, and altogether from a sense of duty. He had inclined to fight on the line of Pipe Creek, to the south of Gettysburg; but Reynolds fell into collision with Lee's advance at Gettysburg, other corps hurried to support, and

Gettysburg became historical. When Grant assumed general command, in 1864, Meade continued to command the Army of the Potomac under him, and mutual good-feeling enabled them to maintain this delicate relation without friction, and with the best results. At the close of the war, being major-general in the regular army, he commanded the military division of the Atlantic until his death at Philadelphia, Nov. 6, 1872.

MEADE CENTRE, the county-seat of Meade county, Kan.

MEADVILLE, the county-seat of Franklin county, Miss.

MEADVILLE, the county-seat of Crawford county, Penn., on the left bank of French Creek, a tributary of the Alleghany River, and at the junction of the Franklin branch with the main line of the New York, Pennsylvania and Ohio Railroad, 102 miles from Salamanca. It is a well-built town, maintains a large trade with the oil regions, and has railway and other machine works, glass works, woolen mills and paper mills. The "Chautauquan" is published here, and here is located the "Century Press," with all its departments. The public schools of Meadville are of the best. Here, beside Allegheny College, with 250 students and a library of 12,500 volumes, is the Meadville Theological School (Unitarian), with a library of 30,000 volumes. A system of water-works, natural gas for fuel, and electric-light plants add to the natural advantages of the city. The population in 1890 was 9,520.

MEAGHER, Thomas Francis, Irish patriot, was born in Waterford, Aug. 3, 1823, son of a wealthy merchant who represented Waterford for several years. He had his education at the Jesuit College of Clongowes Wood, in Kildare, and at Stonyhurst, and early devoted himself to the patriotic cause as a prominent and fearless member of the Young Ireland party. In 1848 he was sentenced to death under the "Treason-felony" act, but was sent for life to Van Diemen's Land instead. He made his escape in 1852, studied law in the United States, but on the outbreak of the war volunteered into the national army. In 1861 he organized the "Irish Brigade" for the Federals, and distinguished himself by his courage in the Seven Days' battles around Richmond, at the second battle of Bull Run, Fredericksburg and Antietam. After the war he became secretary of Montana Territory, and while taking measures as temporary governor to keep the hostile Indians in check, fell from the deck of a steamboat into the Missouri, near Fort Benton, and was drowned, July 1, 1867.

MEAL-TUB PLOT, a conspiracy fabricated in 1679 by Thomas Dangerfield, to gain credit as an informer equal to that of Titus Oates and Bedloe. The son of a Roundhead farmer, he was born about 1650 at Waltham in Essex, and he had first started with the baseless assertion that the Presbyterians were conspiring to destroy the government and set up a republic. When this was discovered to be a lie he was flung into Newgate, whereupon he rounded at once upon the Roman Catholics, declaring that the pretended Presbyterian plot was only a cover for their own design upon the king's life, and that the papers would be found concealed at the bottom of a meal-tub in the house of one Mrs. Cellier, who, together with Lady Powis, was actually tried and acquitted for the plot. Dangerfield himself was whipped and pilloried in June, 1685, and on his way back from Tyburn was killed by a blow in the eye from the cane of a barrister, Robert Frances, who was executed for the murder.

MEANY, Stephen Joseph, born in County Clare, Ireland, December, 1825; highly educated, a trained stenographer, and successful journalist. In 1843, when on the Dublin police force, he declined to obey the government's orders to report the speeches of Daniel O'Connell. He resigned and acted as O'Connell's reporter for the "Freeman's Journal." A member of the Young Ireland movement of 1848, founder of the Fenian Brotherhood, sentenced to fifteen years' imprisonment on account of the part taken by him in the Fenian uprising of 1866, and pardoned after a year's service, Meany came to the United States and in 1868 established "The Commercial" in Toledo, Ohio. Going to New York city in 1869, he entered upon the duties of Irish correspondent and leader-writer on several papers of that city. Later he removed to Waterbury, Conn., where he died in 1887.

MEASON, Malcolm Ronald Laing, was born at Edinburgh, in 1824, and educated in France, and at St. Gregory's College, Downside, near Bath. He entered the army, in 1839, as ensign of the 40th regiment, and served through the second Afghan and the Gwalior campaigns in India, was very severely wounded, and received two medals. He joined the 10th Hussars in 1846, and sold out in 1851. From the latter year to 1854 he was editor of the "Bombay Telegraph and Courier." In 1855 he was sent to Paris by the "Daily News," in conjunction with Mr. Blanchard Jerrold, as one of the special correspondents for the Paris Exhibition of that year. From 1855 to 1870 he was a frequent contributor to the "Daily News," "Household Words," and "All the Year Round." From 1866 to 1870 he was editor of "The Weekly Register." In 1870 he went abroad as special correspondent of the "New York Herald" with the French army. After Sedan he accepted an offer from the "Daily Telegraph," and remained in France as special correspondent of that paper until the end of the war, and afterwards, for two years, as correspondent for the same journal at Paris and Versailles. He joined the staff of "The Hour" in 1873. In 1865 he published *The Bubbles of Finance*, and in 1866 *The Profits of Panics*, being both descriptions from life of the joint-stock swindles of the day. In 1868 he published a small volume on *Turf Frauds*. He has contributed to "The Month," "The Dublin Review," "Belgravia," "Fraser," "Macmillan," "The Whitehall Review," and other periodicals.

MECHANIC FALLS, or Mechanic's Falls, a post-village of Androscoggin county, Me., thirty-three miles north of Portland. Paper, rifles, shoes, cheese, harness, organs, and furniture are manufactured here. There is also a corn-canning establishment. Pop., 2,500.

MECHANICSBURG, a post-village of Champaign county, Ohio, seventeen miles northwest of Springfield. Pop., 1,459.

MECHANICSBURG, a post-borough of Cumberland county, Pa., eight miles west of Harrisburg. It contains a foundry, spoke and bending works, door and sash factories, Irving Female College, and Cumberland Valley Institute. Pop., 3,691.

MECHANICSVILLE, a post-village and a railroad junction of Saratoga county, N. Y., eighteen miles northeast of Schenectady. It manufactures linen thread. Pop., 2,679.

MECKLENBURG-STRELITZ, Grand Duke of (Frederick William Charles George Ernest Adolphus Gustavus), a lieutenant-general in the Prussian army, born Oct. 17, 1819; married, June 28, 1843, the Princess Augusta Carolina Charlotte Elizabeth Maria Sophia Louisa of Cambridge, daughter of the late Duke of Cambridge. He succeeded his father, Sept. 6, 1860, and has one son, George Adolphus Frederick Augustus Victor Ernest Gustavus William Wellington, born July 22, 1848.

MEDEAH, a town of Algeria, forty miles southwest of Algiers. It is supplied with water by means of an aqueduct. Pop., 3,620.

MEDELLIN, a town (pop., 1,250) of Spain, on the Gaudiana. It is worthy of mention as the birthplace of Cortez.

MEDFORD, the county-seat of Middlesex county, Mass., is an important and prosperous manufacturing city and seat of Tuft's College. See Britannica, Vol. XV, p. 777. Pop. (1890), 11,079.

MEDFORD, the county-seat of Taylor county, Wis. Pop., 1,193.

MEDIA, the county-seat of Delaware county, Penn. Pop., 2,736.

MEDICAL ASSOCIATION, AMERICAN. The number of physicians belonging to the school represented by this organization in 1892 is estimated at 84,000. It comprises 100 medical colleges, 1,800 professors and instructors, and about 10,000 students in attendance in the colleges. About 4,000 of the latter received the degree of M.D. in 1892. The president of the association is Dr. Hunter McGuire, of Virginia, and the permanent secretary is Dr. Wm. B. Atkinson, of Philadelphia, Pa. The colleges had libraries equaling 50,000 volumes. Their buildings, lands, and scientific apparatus amounted to four millions of dollars in value.

Forty-one States have State medical societies. The American Medical Association, the parent body, so to speak, has a membership of over 5,000. In addition, there are a number of special organizations, such as the American Academy of Medicine, composed only of medical graduates who have received a degree in letters prior to graduation; membership, about 600; American Association for the Study and Cure of Inebriates, American Climatological Association, American Dermatological Association, American Gynæcological Association, American Laryngological Association, American Neurological Association, American Ophthalmological Association, American Otological Association, American Association of Pædiatrics, and American Public Health Association.

In many of the States the county medical societies alone are represented in the State body, but in others, particularly those of the West, the counties are poorly organized, and the State body is made up independently. The aggregate membership of these State societies at present is not far from 40,000. The aggregate number of county and district medical societies is 700. All these are in association with and entitled to send delegates to the American Medical Association. The number of hospitals, whether attached to colleges or otherwise, is about 730.

MEDICAL COLLEGES OF THE UNITED STATES. There are at present (1893) over 100 medical schools in active operation in the United States, with about 1,800 professors. To this number we must add ten colleges of eclectic and 13 of homeopathic medicine, 18 dental, and 17 pharmaceutical colleges, making a total of 148. In 1893 the standards of the leading medical colleges in the United States were high as to requirements, and marked progress has been made in medical teaching.

The following list gives the most notable of the medical colleges in the United States in the order in which they have been organized:

| Medical Colleges. | Founded. | Professors. | Graduates. |
|---|---|---|---|
| Medical Department of the University of Pennsylvania, Philadelphia | 1765 | 53 | 101 |
| Harvard Medical School, Boston | 1782 | 52 | 59 |
| College of Physicians and Surgeons, New York | 1807 | 53 | 115 |
| School of Medicine of the University of Maryland | 1807 | 19 | 17 |
| Medical College of Ohio | 1819 | 13 | 100 |
| Jefferson Medical College, Philadelphia | 1825 | 19 | 215 |
| Medical Department of the University of Virginia | 1825 | 5 | 14 |
| Medical Department of the University of Louisville | 1837 | 13 | 84 |
| Medical Department of the University of the City of New York | 1840 | 27 | 213 |
| Missouri Medical College, St. Louis | 1840 | 18 | 103 |
| Rush Medical College, Chicago | 1843 | 37 | 166 |
| Woman's Medical College of Pennsylvania, Philadelphia | 1850 | 15 | 26 |
| Cincinnati College of Medicine and Surgery | 1851 | 14 | 14 |
| New England Female Medical College, Boston | 1856 | ..... | ..... |
| Bellevue Hospital Medical College, New York | 1861 | 28 | 149 |
| Woman's Medical College of New York Infirmary | 1868 | 20 | 9 |
| College of Physicians and Surgeons, Baltimore | 1872 | 10 | 127 |
| Woman's Medical College of Chicago | 1870 | 28 | 21 |
| Woman's Medical College of Baltimore | 1882 | 17 | 5 |

It must be remarked here, that Philadelphia, the seat of the first medical college in the United States, is also the seat of the first woman's medical college. After Philadelphia, come Boston, New York, Chicago and Baltimore in establishing colleges for women.

Of the now existing homeopathic schools in the United States the first one, in point of time, is the "Hahnemann Medical College of Philadelphia." It was founded by Dr. Constantine Hering, and incorporated in 1848 as the "Homeopathic Medical of Pennsylvania." The first class consisted of 15 students. In 1867 a rival institution was organized, entitled the "Hahnemann Medical College of Philadelphia." These two schools were combined in 1869, retaining the name of the latter, but working under the charter of the former. Since that time the college has been prosperous. It graduated 1,648 students up to 1886.

A third school of medicine in America is the "Eclectic." It claims to adopt all that is of proved value in either of the other two systems, and to hold itself free to vary in accordance with every new discovery. To this it adds the employment of "specifics," which are nearly always from the vegetable kingdom, and are directed to special pathological conditions, on the principle that certain diseases generate similar morbid products which may be excreted from the system by the use of these "specifics." The first regular eclectic school was instituted at Cincinnati in 1843, under the title of the "Eclectic Medical Institute." Up to 1875 this school had matriculated 5,375 students and graduated 1,804. In 1882 it had 8 professors and 272 students, of whom 100 graduated. In 1866 followed the establishment of the Eclectic Medical College of the City of New York, with 9 professors, and in 1878 that of the United States Medical College of

New York, with 13 professors. Similar colleges exist now in Chicago, St. Louis, Atlanta and Oakland, Cal. In the year 1886 the eclectic system had in all about 100 professors and on an average 312 graduates per annum. Yet eclecticism cannot be said to be in a very flourishing condition.

The best-known homeopathic colleges of the United States are the following, with dates of their organization, up to 1876:

| Colleges. | Organized. |
|---|---|
| Hahnemann Medical College of Philadelphia | 1848 |
| Cleveland Homeopathic Hospital College | 1849 |
| Pennsylvania Medical University, Philadelphia | 1853 |
| Hahnemann Medical College of Chicago | 1855 |
| Homeopathic Medical College of St. Louis, Mo | 1858 |
| New York Homeopathic Medical College | 1860 |
| New York Homeopathic Medical College for Women | 1863 |
| Boston University School of Medicine | 1869 |
| Homeopathic Medical College of Detroit | 1871 |
| Pulte Medical College, Cincinnati | 1872 |
| Homeopathic Medical College of the University of Michigan | 1875 |
| Chicago Homeopathic College | 1876 |

The great drawback of many of the medical colleges is the fact that they cannot give any valuable clinical instructions, because they have no access to the large hospitals, only those of the largest cities being connected with such hospitals. Many of them draw students by low prices and easy examinations. These inducements, together with the desire of many young Americans to become doctors at little cost of money, time, and study, has forced some of the best medical schools to make their courses less thorough and their examinations comparatively easy; for they have to compete with the third-rate colleges for patronage and their existence depends on the public patronage. The consequence is that the United States has now more physicians in proportion to the population than any other country in the world. In 1880 there was one physician for every 584 inhabitants. The first-class medical colleges, as those in New York, Philadelphia and Boston, have instituted a three years' course of study. But the majority of the medical colleges throughout the country have only a two years' course of about twenty weeks' duration each.

MEDICAL LAKE, in Spokane county, Washington, so-called from the peculiar character of its water. A good quality of soap is made from the water by condensation.

MEDICINE LODGE, the county-seat of Barber county, Kan. Pop., 1,095.

MEDICK (*Medicago*), a genus of plants of the natural order *Leguminosæ*, sub-order *Papilionaceæ*, nearly allied to clover, but distinguished from that and kindred genera by the sickle-shaped, or, in most species, spirally twisted legume. The species, which are very numerous, are mostly annual and perennial herbaceous plants, with leaves of three leaflets like those of clover, and are natives of temperate and warm climates. They afford good green food for cattle, and some of them are cultivated like the clovers for this use, amongst which the most important is the Purple Medick, of Lucerne. Besides this, the Black Medick or Nonsuch (*M. lupulina*) is one of the most generally cultivated.

MEDILL, Joseph, born in New Brunswick, Canada, April 6, 1823; removed to Ohio when a boy, and practiced law in Massillon. He founded a Free Soil and a Whig newspaper in Cleveland, Ohio, and in 1855 purchased an interest in the "Chicago Tribune," of which he is now (1893) the editor. In 1871 he was elected mayor of Chicago. He was also a member of the Illinois constitutional convention in 1870, and afterward of the civil service commission, and is credited with having refused several appointments as foreign minister.

MEDINA, a post-village of Orleans county, N. Y., on the Erie Canal. It has manufactories of flour, carriages, pumps and farming tools.

MEDINA, a post-village, the county-seat of Medina county, Ohio. It contains a normal school, flour, saw and planing mills, a foundry and other manufactories. Pop. (1890), 2,100.

MEDINA, Antonio, born free, of African parents, in Havana in 1824. He established a free school for boys, and did much for the elevation of his race. He has written a volume of poetry and several dramas. He died in 1884.

MEDING, Oskar, a German novelist, who writes under the pseudonym, "Gregor Samarow," was born April 11, 1829, at Königsberg, being the son of the governor of East Prussia. He studied law in his native town, at Heidelberg and Berlin, from 1848 to 1851, when he became an advocate at Marienwerder. At a later period he was employed in the magistracy and administration; and in 1859 he quitted the public service of Prussia and joined that of Hanover. Sent on a mission to the Elector of Hesse, in 1866, he returned to Hanover at the time of the Prussian invasion of that country; rejoined the king, who was with the army, and, after the catastrophe of Langenesalza, followed the king to Vienna. He went to Paris in the following year as the representative of the interests of the deposed king. In 1870 he gave in his adhesion to the Prussian government, and after residing two years in Switzerland, and at Stuttgart, he settled in Berlin, where, keeping wholly aloof from politics, he began to write his personal reminiscences, in the form of novels, under the pseudonym of "Gregor Samarow."

MEDLEY, John, D.D., bishop of Fredericton, and metropolitan of Canada, born in 1804; was educated at Wadham College, Oxford, where he graduated B.A. in honors in 1826, and M.A. in 1830. He was for several years vicar of St. Thomas', Exeter, and prebendary of that cathedral, and in 1845 was consecrated first bishop of Fredericton. His diocese included the entire province of New Brunswick. In 1879 he became metropolitan of Canada. He died in 1892.

MEDMENHAM, a village of Buckinghamshire, near the Thames, 3 miles southwest of Marlow. Here stood a Cistercian abbey (1204); and here, soon after the middle of the 18th century, Sir Francis Dashwood, afterwards Lord le Despenser (1708–81), founded his mock brotherhood of "Franciscans," whose motto was the familiar inscription on Rabelais' abbey of Thelema, "Fay ce que voudras," and two of whose twelve members were John Wilkes and Paul Whitehead, the poet.

MEEANEE, or Miani, a village in Sind, India, on the Indus, 6 miles north of Hyderabad, was the scene of a battle between Sir Charles Napier with 2,800 men, and a Baluch army, 22,000 strong, on Feb. 17, 1843. The latter were totally routed, losing 5,000 men; the British loss was 256. The result of this victory was the conquest and annexation of Sind.

MEEK, Alexander Beaufort (1814–65), began the practice of law in Tuscaloosa, Ala., in 1835. Served in the Seminole war, and was judge of the county court of Tuscaloosa. When a member of the State legislature, he secured the passage of the bill establishing the public schools of Alabama. His later years he spent in literary work.

MEEK, Fielding Bradford, an American paleontologist, born at Madison, Ind., in 1817, died at Washington, D. C., in 1876. He first engaged in

mercantile pursuits until 1848, when he became an assistant in the United States geological survey of Iowa, Wisconsin and Minnesota. During 1852-58 he assisted James Hall in his paleontological work of the State of New York, except in summers, when he was engaged in field-work. After 1858 he resided in Washington, D. C., and devoted his time to investigating the organic remains gathered by the Government exploring expeditions. The invertebrate paleontology of the Rocky Mountains, as developed by the survey of Prof. Hayden, was intrusted to Mr. Meek. He also studied the paleontology of Illinois, Ohio, California, and of several of the Territories. He wrote several works on geological topics.

MEEKER, Joseph R., artist, was born in New Jersey, April 21, 1827, and exhibited at the American Art Union about 1850. He removed to St. Louis and devoted his attention to landscape painting, in which he became very successful.

MEGALONYX, a large fossil edentate of the United States, smaller than the Megatherium.

MEGRIMS and VERTIGO, terms usually employed when a horse at work reels, and then either stands for a minute dull and stupid, or falls to the ground, lying for a time partially insensible. These attacks come on suddenly, and are most frequent during hot weather when the animal is doing heavy work. Liability to megrims constitutes unsoundness, and usually depends upon the circulation through the brain being temporarily disturbed by the presence of tumors, or by weakness of the heart's action.

MEIAPONTE, a town of Brazil, 65 miles east of Goyas, on the river Almas. It has five churches, a hospital, a Latin and primary school, and many distilleries and potteries, and is well situated for trade.

MEIGGS, Henry (1811–1877), an American contractor. For several years he was in the lumber business in New York city, but in the financial crisis of 1854 his debts amounted to $1,000,000 and he fled to South America. He then engaged in building bridges on the Valparaiso and Santiago road in Chile, and later constructed railroads in that country from which he realized a profit of over $1,500,000. He next undertook the building of six railroads in Peru, three of which he completed, and the remainder were in course of construction when he died. One of these, the Callas, Lima, and Oroya road, ranks among one of the most daring achievements of modern engineering. Before his death Mr. Meiggs met all of his former obligations in the United States.

MEIGS, Charles Delucena (1792–1869), an American physician. He began the practice of medicine in Augusta, Ga., but in 1814 went to Philadelphia. From 1841 to 1861 he was professor of obstetrics and the diseases of women and children in Jefferson Medical College. He published several works in his department of medicine.

MEIGS, James A., born in Philadelphia, July 31, 1829, died Nov. 8, 1879. He held the chair of physiology in the Pennsylvania Medical College, and was also professor of the institutes of medicine in Philadelphia College of Medicine. His articles on craniology and ethnology are of value.

MEIGS, Montgomery C., born in Augusta, Ga., May 3, 1816, graduated at the United States Military Academy in 1836, and was appointed to the artillery, but transferred the following year to the engineer corps. For many years he was occupied in the engineering service on the sea coast and in the construction of the Government works at Washington, D. C., and elsewhere. In May, 1861, he was promoted colonel of the 11th infantry, and the following day was made quartermaster-general of the United States army, with the rank of brigadier-general. This post he held until his retirement from active service in November, 1882. During the whole of the war General Meigs was engaged in directing the equipment and supplies of the armies in the field. In 1876 he was a member of the commission for reorganization of the army, and since his retirement he has served as architect of the pension bureau building at Washington, which was completed in 1887. He was a regent of the Smithsonian Institution. He died in January, 1892.

MEIGS, Return Jonathan (1740–1823), an American soldier. He entered the American army at the beginning of the Revolutionary war, became a major, and in 1777 a colonel. In that year at the head of 170 men he attacked the British troops at Sag Harbor, Long Island, captured ninety prisoners and destroyed twelve vessels without the loss of a man.

MEIGS, Return Jonathan (1765–1825), a United States Senator, son of the preceding. He began the practice of law in Marietta, Ohio, in 1788, and in 1803–4 was chief justice of the State supreme court. In 1807 he was appointed judge of the United States district court of Michigan, and in 1809–10 was a United States Senator from Ohio. From 1810 to 1814 he was governor of his State. He then became Postmaster General in President Madison's cabinet, and continued to hold the office until 1823, when he retired to Marietta to pass the remainder of his life.

MEILHAC, Henri, a French dramatic author, born in Paris in 1832; was educated at the Lycée Louis-le-Grand. From 1852 to 1855 he contributed with pen and pencil to the "Journal pour Rire," and in 1855 his first dramatic efforts, *Satania* and *Garde toi, je me garde* were produced at the Palais Royal, but without much success. In 1860, in collaboration with M. Ludovic Halévy, he wrote *L'Etincelle*, and *Une heure avant l'ouverture*, both played at the Vaudeville, and in 1861, with M. Arthur Delavegne, *La Vertu de Célimène*, produced at the Gymnase, which became very popular, notwithstanding its improbable plot. In conjunction with the above-mentioned authors, M. Meilhac has produced a large number of plays, the chief among them being *La Belle Hélène*, *Barbe Bleu*, *Frou-frou*, etc.

MEISSONIER, Jean Louis Ernest, figure painter, born at Lyons, Feb. 21, 1813, died Jan. 31, 1891. When he was still a child his father established himself as a druggist in Paris; and the son, having resolved upon art as a profession, studied under Jules Potier and Léon Cogniet. His drawings were praised by Johannot, and about 1833–34 he was employed by Curmer, the publisher, on designs for the Royaument Bible and other works. He first made a distinct mark in 1838, and by his illustrations to *Paul and Virginia*, and the *Chaumière Indienne*. In 1834 he began to contribute to the Salon. Two years later he exhibited the first of his various groups of *Chess-Players*. It was followed by a long series of elaborate and successful genre-pictures, in which, with the most careful and finished execution, and with the most perfect verisimilitude of costume and local coloring, the artist depicted the civil and military life of the 17th and 18th centuries, passing to subjects of genre or history taken from the nineteenth century. Among the most celebrated of his military scenes may be named *La Rixe*, purchased by Queen Victoria. He also executed some striking portraits. Finally, we may refer to his design for the decoration of the Panthéon—"the apotheosis of France"—the cartoons of which were exhibited to the commission in 1889. He became a commander of the Legion of Honor in 1867, grand cross 1889, and a member of the institute in 1861,

and he was an honorary member of the Royal Academy.

MELIKOFF, Loris, a Russian general, of Armenian descent, was born in 1824, and received his education at the Lazareff Institute in that city. At an early age he began his military career, joining the Hussars at St. Petersburg. At the time of the Crimean war he had attained to the rank of colonel, and commanded a light cavalry regiment. He was present at the capture of Kars, and was appointed commandant of that town with the rank of general. He also took part in the military operations in the Caucasus, and after the peace he was sent, as governor, to Vladi-Kavkas, in Circassia, in 1860. Some years afterward he obtained an unlimited leave of absence on account of the state of his health. He visited France; resided for some time at Paris; went next to Germany, and was staying at Wiesbaden when the declaration of war by Russia against Turkey recalled him to active service. He was appointed adjutant-general to the Grand Duke Michael, the imperial lieutenant commanding-in-chief the army of the Caucasus. It was in fact Gen. Loris Melikoff who directed all the military operations in a country with which no one was more intimately acquainted than himself. To him in particular was due the capture of Ardaham by the Russian troops, May 17, 1877. He died Dec. 27, 1888.

MELODRAMA, that kind of dramatic performance in which declamation is interrupted from time to time by instrumental music. The name, however, which was first applied to the opera by its inventor, Ottavio Rinuccini, has come to designate a romantic play, depending mainly on sensational incidents, thrilling situations, and an effective dénouement. Great sums are spent in the staging of such pieces, and the costumes, scenery, and mechanical effects are often very striking. The expression "transpontine drama" refers to a time when such plays were indentified with houses on the Surrey side of the Thames; nowadays the home of melodrama in London is to be found in such theaters as Drury Lane and the Adelphi.

MELLON, Mrs. Alfred, known under her maiden name, Miss Sarah Jane Woolgar, born July 8, 1824; made her first appearance in London in the Adelphi theater, in September, 1843, in a farce called *Antony and Cleopatra*, when her merit was recognized, and she found herself high in favor with the London public. She took part in all the Adelphi triumphs from the date of her first appearance till her retirement; indeed, except for very brief engagements, she has appeard at no other London theater. She became the wife of the late Mr. Alfred Mellon, the popular composer.

MELLOR, Sir John, born Jan. 1, 1809, and educated privately, was called to the bar at the Inner Temple in 1833, and went the Midland circuit. In 1851 he was appointed Q.C., and elected a bencher of the Inner Temple, was for some years recorder of Warwick, resigned in 1852, and was appointed in February, 1855, to the recordership of Leicester. He was an unsuccessful candidate, in the Liberal interest, for the borough of Warwick in July, 1852, was elected one of the members for Great Yarmouth in August, 1857, and was returned for Nottingham, as an advanced Liberal, at the general election, in April, 1859. He was nominated a justice of the court of the queen's bench in November, 1861, on the retirement of Sir Hugh Hill, and in November, 1885, by the operation of the Judicature act, he became judge of the high court of justice. He was knighted on his elevation to the judicial bench, from which he retired in 1879. He died April 26, 1887.

MELROSE, a city of Middlesex county, Mass., nine miles north of Boston. It has manufactories of boots and shoes, furniture, silver polish and sewing-machine needles. Pop., 8,519.

MELTING-POINT. The following are some of the most important melting-points, which may also be regarded as the freezing points of the corresponding liquids:

| | Cent. ° | Fah. ° |
|---|---|---|
| Alcohol pure | —130 | —202 |
| Hydrobromic acid | —120 | —184 |
| Strongest sulphuric acid | —116 | —177 |
| Sulphuretted hydrogen | — 85 | —121 |
| Ammonia | — 75 | —103 |
| Sulphurous acid | — 75 | —103 |
| Chloride | — 75 | —103 |
| Carbonic acid | — 70 | — 94 |
| Chloroform | — 70 | — 94 |
| Mercury | — 39-38 | — 38-88 |
| Olive and linseed oil | — 20 | — 4 |
| Bromide | — 7·3 | x19-86 |
| Ice | — 0 | — 32 |
| Glacial acetic acid | 17 | 62-6 |
| Phosphorus | 44-2 | 111 |
| Potassium | 62-5 | 144-5 |
| Sodium | 95-6 | 204 |
| Iodine | 113 | 235 |

| | | Cent. ° | Fah. ° |
|---|---|---|---|
| Sulphur | | 115 | 239 |
| Lithium | | 180 | 356 |
| Solder, about | | 180 | 356 |
| Tin | | 228 | 442 |
| Bismuth | | 267 | 513 |
| Lead | | 334 | 633 |
| Antimony | | 430 | 806 |
| Zinc | | 450 | 842 |
| Magnesium | | | |
| | about | 750 | 1,382 |
| Bronze | " | 900 | 1,652 |
| Silver | " | 1,000 | 1,832 |
| Brass | " | 1,015 | 1,860 |
| Copper | " | 1,100 | 2,012 |
| Iron, white cast | " | 1,100 | 2,012 |
| Iron, gray cast | " | 1,225 | 2,237 |
| Gold, pure | " | 1,250 | 2,282 |
| Steel | " | 1,350 | 2,462 |
| Soft iron | " | 1,550 | 2,822 |
| Manganese | " | 1,600 | 2,912 |
| Platinum | " | 1,800 | 3,272 |
| Iridium | " | 1,950 | 3,542 |
| Osmium | " | 2,500 | 4,532 |

Melting-points beyond about 900° or 1,000° F. are merely approximate and relative.

MELVILLE, the name of an island, a sound and a peninsula in the polar regions of North America. The island is 200 miles long by 130 miles broad. The sound, about 250 miles long by 200 broad, extends southeast of the island and communicates with the Arctic Ocean and with Baffiin Bay.

MELVILLE, George Wallace, born in New York city, Jan. 10, 1841, entered the United States navy as an engineer in July, 1861. He was engineer of the *Jeannette*, which sailed on July 8, 1879, under the command of Lieut. George W. DeLong, on a polar expedition. Melville accompanied DeLong over the ice to Bennett Island after the sinking of the *Jeannette*, in June, 1881, and after the division of the party he commanded one of the *Jeannette's* boats, which reached the mouth of the Lena river in September of that year. Melville afterward discovered the remains of DeLong and his eleven companions, and, after his return to the United States, he was appointed engineer-in-chief in the United States navy with the rank of commodore. He is the author of *In the Lena Delta*, an account of the voyage of the *Jeannette*.

MELVILLE, Herman, author, was born in New York city, Aug. 1, 1819. In 1837 he went to sea as a common seaman, to Liverpool, and several years later sailed around Cape Horn for a whaling cruise in the South Pacific Ocean. But as the treatment to which he was subjected was harsh and forbidding, he, with a companion, deserted when the vessel reached one of the Marquesas Islands. Here the two mariners were held captive for several months. Altogether Melville spent about two years among the islands of the Pacific Ocean. In 1850 he removed to Pittsfield, Mass., but subsequently returned to New York city, where he became employed at the custom house. His adventures formed the basis of his earliest work, *Typee* (New York, 1846), and were further related in *Omoo* (1847). In both books novel adventure is apparently mingled with romance, which secured for them an extensive sale. He died Sept. 28, 1891.

MEMMINGER, Charles Gustavus, born in Würtemberg, Germany, Jan. 9, 1803; came to the

United States when very young and settled in South Carolina. In 1836 he was elected to the legislature of that State, in which he sat until 1852. From February, 1861, until June, 1864, he was secretary of the treasury in the Confederate government. After his resignation he lived in retirement, and died at Charleston, March 7, 1888.

MEMPHIS, county-seat of Scotland county, Missouri, containing flouring mills. Pop. (1890), 1,780.

MEMPHIS, a city of Tennessee, the commercial metropolis of West Tennessee, and the most important commercial city between St. Louis and New Orleans. In addition to the facilities afforded by the Mississippi River, on which it is situated, numerous lines of railroads bring the products of a large section of country to its wharves. The city is handsomely built on a bluff overlooking the river. It is one of the most extensive cotton markets of the country, the shipments of cotton amounting to over 400,000 bales per annum. The principal manufactures are iron, iron-goods, cotton-seed oil, lumber, tobacco, farm-machinery, etc. Memphis has a number of excellent public and private schools and seminaries. Population in 1880, 33,592; in 1890, 64,495. See Britannica, Vol. XV, pp. 847, 848.

MENABREA, Luigi Federico, Marquis Vall-Dora, an Italian statesman, born in Chambery, France, in 1809. He was professor of engineering in the military academy at Turin. Afterwards he served in the Italian ministry of war and of the interior. In the war against Austria in 1859 he was chief of staff, and conducted the siege of Gaëta. In 1861 he was made count, and in 1867 he was minister of foreign affairs. In 1875 he was created Marquis of Vall-Dora, and in 1876 he served as ambassador to England. He is an accomplished mathematician and engineer, and has published *Le Génie Italien dans la Campagne 1860–61* (1866).

MENARD, Pierre, born in Quebec, in 1767; removed to Kaskaskia, Ill., in 1788; became a United States district judge and member of the Territorial legislature, and in 1819 became the first lieutenant-governor of the new State of Illinois. Died in 1845.

MENARD, René, a French missionary, was born in Paris in 1604, and came to Montreal in 1640. For more than twenty years he was active as a missionary among the Algonquin, Cayuga, and Oneida Indians of Central New York. He died while on a journey to visit some Huron tribes on the Black river.

MENASHA, a city and railroad center of Winnebago county, Wis., eighteen miles north of Oshkosh. It has a number of manufactories. Population, 4,581.

MENDELEEFF, Dmitri Ivanovitch, a Russian chemist, born at Tobolsk, Feb. 7, 1834; professor of chemistry in the University of St. Petersburg in 1866.

MENDENHALL, Thomas C., born in Ohio, October 4, 1841; became in 1873 professor of physics and mechanics in Ohio University, and occupied that position for five years. From 1878 until 1881 he was occupied with meteorological observations in Japan, and on his return resumed his old position. In 1884 he became connected with the United States signal service, and in 1886 accepted the presidency of a Polytechnic Institute in Indiana.

MENDÈS, Catulle, was born at Bordeaux in 1840. In 1860 he established in Paris *La Reine Fantaisiste*, in which he published *Le Roman d'une Nuit*, a drama in verse, but being under age he was condemned to two months' imprisonment and a fine of 500 francs. He has written several lyrics and dramas.

MENDOTA, a city of La Salle county, Ill., containing an organ-factory and iron-foundry. Pop., 3,542.

MENOMINEE, a city, the county-seat of Menominee county, Mich., situated on Green Bay, at the mouth of the Menominee River. Iron-mining, marble-quarrying and lumber-shipping are the chief industries. Pop. (1890), 10,630.

MENOMONIE, a city, the county-seat of Dunn county, Wis., about twenty-five miles northwest of Eau Claire. It is extensively engaged in the fur-trade, has manufactories of iron, machinery, carriages, sash and blinds, and enjoys excellent educational facilities. Pop. (1890), 5,491.

MENZEL, Adolph, a German painter, lithographer, illustrator, and engraver, born at Breslau, Dec. 8, 1815. He is best known for his drawings and oil-paintings illustrative of the times of Frederick the Great and William I., Emperor—pictures characterized by historical fidelity, strong realistic conception, originality, and humor. His *Adam and Eve; Christ Among the Doctors*, and *Christ Expelling the Money-Changers*, are also notable pictures.

MERCADANTE, Saverio (1798–1870), an Italian composer, born at Altamura, June 26, 1797, studied music at Naples, and began his career as a violinist and flutist. In 1818 he produced the first of some sixty operas. From 1827 to 1831 he was in Spain; in 1833 he was appointed musical director in the cathedral at Novara, and in 1840 of the conservatory of music at Naples. He died in that city Dec. 17, 1870—blind since 1861.

MERCED, a city, the county-seat of Merced county, Cal., on the Central Pacific Railroad, 152 miles southeast of San Francisco. Pop., 2,009.

MERCER, a post-borough, the county-seat of Mercer county, Pa., sixty miles northwest of Pittsburg. Pop., 2,138.

MERCER, Charles Fenton (1778–1858), an American soldier. In 1798 he was commissioned captain in the United States army, but subsequently practiced law in Fredericksburg, Va. From 1810 to 1817 he was a member of the legislature, and then until 1840 was a member of Congress. During the war of 1812 he was aide to the governor of Virginia, and in command of the defenses at Norfolk.

MERCER, Hugh (1720–1777), an American soldier. He served in the French and Indian war of 1755, and in 1758 was made a lieutenant-colonel. In 1776 he was appointed colonel of the 3rd Virginia regiment, and the following year was chosen by Congress brigadier-general. He was mortally wounded in the night march on Princeton, in which he commanded the advance.

MERCERSBURG, a post-borough of Franklin county, Pa., ten miles northwest of Greencastle. It contains Mercersburg College, and was formerly the seat of Marshall College and a theological seminary of the German Reformed church.

MEREDITH, George, an English novelist and poet, born in Hampshire, Feb. 12, 1828, and made his first appearance as an author in 1851 in a little volume of poems. This was followed by *The Shaving of Shagpat: an Arabian Entertainment*, a highly original tale, in burlesque imitation of the manner of the Eastern story-teller. The series of Mr. Meredith's greater and more characteristic works began in 1859 with *The Ordeal of Richard Feverel: a History of a Father and a Son*, a tragic romance, dealing with the larger problems of education, especially in its ethical aspects. *Beauchamp's Career* is perhaps the most perfectly constructed of all the series. *Diana of the Crossways* is by general consent the most charming of Mr. Meredith's novels.
